# Notes on Schubert, Grothendieck and Key polynomials 

ANATOL N. KIRILLOV<br>Research Institute of Mathematical Sciences (RIMS )<br>Kyoto 606-8502, Japan<br>URL: http://www.kurims.kyoto-u.ac.jp/~ kirillov<br>and<br>The Kavli Institute for the Physics and Mathematics of the Universe ( IPMU ), 5-1-5 Kashiwanoha, Kashiwa, 277-8583, Japan

To the memory of Alexander Grothendieck
(1928-2014).

We introduce

- certain finite dimensional algebras denoted by $\mathcal{P} \mathcal{C}_{n}$ and $\mathcal{P} \mathcal{F}_{n, m}$ which are certain quotients of the plactic algebra $\mathcal{P}_{n}$, had been introduced by A. Lascoux and M.-P. Schützenberger [28]; we show that $\operatorname{dim}\left(\mathcal{P} \mathcal{F}_{n, k}\right)$ is equal to the number of symmetric plane partitions fit inside the box $n \times k \times k, \operatorname{dim}\left(\mathcal{P} \mathcal{C}_{n}\right)$ is equal to the number of alternating sign matrices of size $n \times n$, moreover,
$\operatorname{dim}\left(\mathcal{P F}_{n, n}\right)=\operatorname{TSPP}(n) \times \operatorname{TSSCPP}(n), \operatorname{dim}\left(\mathcal{P F}_{n, n+1}\right)=\operatorname{TSPP}(n) \times \operatorname{TSSCPP}(n+$ 1), $\operatorname{dim}\left(\mathcal{P} \mathcal{F}_{n+2, n}\right)=\operatorname{dim}\left(\mathcal{P} \mathcal{F}_{n, n+1}\right), \operatorname{dim}\left(\mathcal{P} \mathcal{F}_{n+3, n}\right)=\frac{1}{2} \operatorname{dim}\left(\mathcal{P F} \mathcal{F}_{n+1, n+1}\right)$, and study
- decomposition of the Cauchy kernels corresponding to the algebras $\mathcal{P} \mathcal{C}_{n}$ and $\mathcal{P} \mathcal{F}_{n, m}$; as well as introduce
- polynomials which are common generalizations of the (double) Schubert, $\beta$ - Grothendieck, Demazure (known also as key polynomials), (plactic) Key-Grothendieck, (plactic) Stanley and stable $\beta$ - Grothendieck polynomials.

Using a family of the Hecke type divided difference operators we introduce polynomials which are common generalizations of the Schubert, $\beta$-Grothendieck, dual $\beta$ Grothendieck, $\beta$-Demazure-Grothendieck, and Di-Francesco-Zin-Justin polynomials.

We also

- introduce and study some properties of the double affine nilCoxeter algebras and related polynomials,
- put forward a quantum version of the Knuth relations and plactic algebra.

Keywords Plactic monoid and reduced plactic algebras; nilCoxeter and IdCoxeter algebras; Schubert, $\beta$-Grothendieck, Key and (double) Key-Grothendieck polynomials ; Cauchy's type kernels and symmetric, totally symmetric plane partitions, and alternating sign matrices; double affine nilCoxeter algebras.

## 1 Introduction

The Grothendieck polynomials had been introduced by A. Lascoux and M.-P. Schützenberger in [29] and studied in detail in [37]. There are two equivalent versions of the Grothendieck polynomials depending on a choice of a basis in the Grothendieck ring $K^{\star}\left(\mathcal{F} l_{n}\right)$ of the complete flag variety $\mathcal{F} l_{n}$. The basis $\left\{\exp \left(\xi_{1}\right), \ldots, \exp \left(\xi_{n}\right)\right\}$ in $K^{*}\left(\mathcal{F} l_{n}\right)$ is a one choice, and another choice is the basis $\left\{1-\exp \left(-\xi_{j}\right), 1 \leq j \leq n\right\}$, where $\left.\xi_{j}, 1 \leq j \leq n\right\}$ denote the Chern classes of the tautological linear bundles $L_{j}$ over the flag variety $\mathcal{F} l_{n}$. In the present paper we use the basis in a deformed Grothendieck ring $K^{*, \beta}\left(\mathcal{F}_{n}\right)$ of the flag variety $\mathcal{F} l_{n}$ generated by the set of elements $\left\{x_{i}=x_{i}^{(\beta)}=1-\exp \left(\beta \xi_{i}\right), i=1, \ldots, n\right\}$. This basis has been introduced and used for construction of the $\beta$-Grothendieck polynomials in [8], [9].

A basis in the classical Grothendieck ring of the flag variety in question corresponds to the choice $\beta=-1$. For arbitrary $\beta$ the ring generated by the elements $\left\{x_{i}^{(\beta)}, 1 \leq i \leq n\right\}$ has been identified with the Grothendieck ring corresponding to the generalized cohomology theory associated with the multiplicative formal group law $F(x, y)=x+y+\beta x y$, see [15]. The Grothendieck polynomials corresponding to the classical $K$-theory ring $K^{\star}\left(\mathcal{F} l_{n}\right)$, i.e. the case $\beta=-1$, had been studied in depth by A. Lascoux and M.-P. Schützenberger in 30]. The $\beta$-Grothendieck polynomials has been studied in [8, [10], [15].

The plactic monoid over a finite totally ordered set $\mathbb{A}=\{a<b<c<\ldots<d\}$ is the quotient of the free monoid generated by elements from $\mathbb{A}$ subject to the elementary Knuth transformations [21]

$$
\begin{equation*}
b c a=b a c \quad \& a c b=c a b, \quad \text { and } \quad b a b=b b a \& a b a=b a a, \tag{1.1}
\end{equation*}
$$

for any triple $\{a<b<c\} \subset \mathbb{A}$.
To our knowledge, the concept of "plactic monoid" has its origins in a paper by C.Schensted [52], concerning the study of the longest increasing subsequence of a permutation, and a paper by D. Knuth [21], concerning the study of combinatorial and algebraic properties of the Robinson-Schensted correspondence ${ }^{1}$.

As far as we know, this monoid and the (unital) algebra $\mathcal{P}(\mathbb{A})$ corresponding to that monoid ${ }^{2}$, had been introduced, studied and used in 53], Section 5, to give the first complete proof of the famous Littlewood-Richardson rule in the theory of Symmetric functions. A bit later this monoid, was named the "monoïde plaxique" and studied in depth by A. Lascoux and M.-P. Schützenberger [28]. The algebra corresponding to plactic monoid is commonly known as plactic algebra. One of the basic properties of the plactic algebra [53] is that it contains the distinguish commutative subalgebra which is generated by noncommutative

[^0]elementary symmetric polynomials
\[

$$
\begin{equation*}
e_{k}\left(\mathbb{A}_{n}\right)=\sum_{i_{1}>i_{2}>\ldots>i_{k}} a_{i_{1}} a_{i_{2}} \cdots a_{i_{k}}, \quad k=1, \ldots, n, \tag{1.2}
\end{equation*}
$$

\]

see e.g. [53, Corollary 5.9, 7].
We refer the reader to nice written overview [40] of the basic properties and applications of the plactic monoid in Combinatorics.

It is easy to see that the plactic relations for two letters $a<b$, namely,

$$
a b a=b a a, \quad b a b=b b a,
$$

imply the commutativity of noncommutative elementary polynomials in two variables. In other words, the plactic relations for two letters imply that

$$
b a(a+b)=(a+b) b a, a<b
$$

It has been proved in [7] that these relations together with the Knuth relations (1.1) for three letters $a<b<c$, imply the commutativity of noncommutative elementary symmetric polynomials for any number of variables.

In the present paper we prove that in fact the commutativity of nocommutative elementary symmetric polynomials for $n=2$ and $n=3$ implies the commutativity of that polynomials for all $n$, see Theorem $2.233^{3}$.

One of the main objectives of the present paper is to study combinatorial properties of the generalized plactic Cauchy kernel

$$
\begin{equation*}
\mathcal{C}\left(\mathfrak{P}_{n}, U\right)=\prod_{i=1}^{n-1}\left\{\prod_{j=n-1}^{i}\left(1+p_{i, j-i+1} u_{j}\right)\right\}, \tag{1.3}
\end{equation*}
$$

where $\mathfrak{P}_{n}$ stands for the set of parameters $\left\{p_{i j}, \quad 2 \leq i+j \leq n+1, i>1, j>1\right\}$, and $U:=U_{n}$ stands for a certain noncommutative algebra we are interested in, see Section 5.

We also want to bring to the attention of the reader on some interesting combinatorial properties of rectangular Cauchy kernels

$$
\mathcal{F}\left(\mathfrak{P}_{n, m}, U\right)=\prod_{i=1}^{n-1}\left\{\prod_{j=m-1}^{1}\left(1+p_{i, \overline{i-j+1}}(m) u_{j}\right)\right\},
$$

where $\mathfrak{P}_{n, m}=\left\{p_{i j}\right\}_{\substack{1 \leq j \leq n \\ 1 \leq j \leq m}}$.
We treat these kernels in the (reduced) plactic algebras $\mathcal{P} \mathcal{C}_{n}$ and $\mathcal{P} \mathcal{F}_{n, m}$ correspondingly. The algebras $\mathcal{P} \mathcal{C}_{n}$ and $\mathcal{P} \mathcal{F}_{n, m}$ are finite dimensional and have bases parameterized by certain Young tableaux described in Section 5.1 and Section 6 correspondingly. Decomposition of the

[^1]rectangular Cauchy kernel with respect to the basis in the algebra $\mathcal{P} \mathcal{F}_{n, m}$ mentioned above, gives rise to a set of polynomials which are common generalizations of the (double) Schubert. $\beta$-Grothendieck, Demazure and Stanley polynomials. To be more precise, the polynomials listed above correspond to certain quotients of the plactic algebra $\mathcal{P} \mathcal{F}_{n, m}$ and appropriate specializations of parameters $\left\{p_{i j}\right\}$ involved in our definition of polynomials $U_{\alpha}\left(\left\{p_{i j}\right\}\right)$, see Section 6.

As it was pointed out in the beginning of Introduction, the Knuth (or plactic) relations (1.1) have been discovered in [21] in the course of the study of algebraic and combinatorial properties of the Robinson-Schensted correspondence. Motivated by the study of basic properties of a quantum version of the tropical/geometric Robinson-Schensted-Knuth correspondence -work in progress, but see [1], [18], [19], [47, [48] for definition and basic properties of the tropical/geometric RSK, - the author of the present paper came to a discovery that a certain deformations of the Knuth relations preserve the Hilbert series (resp.the

More precisely, let $\left\{q_{2}, \ldots, q_{n}\right\}$ be a set of (mutually commuting) parameters, and $\mathbb{U}_{n}:=$ $\left\{u_{1}, \ldots, u_{n}\right\}$ be a set of generators of the free associative algebra over $\mathbb{Q}$ of rank $n$. Let $Y, Z \subset[1, n]$ be subsets such that $Y \cup Z=[1, n]$ and $Y \cap Z=\emptyset$. Let us set $p(a)=0$, if $a \in Y$ and $p(a)=1$, if $a \in Z$.
Define super quantum Knuth relations among the generators $u_{1}, \ldots, u_{n}$ as follows: $S P L_{q}$ :
$(-1)^{p(i) p(k)} q_{k} u_{j} u_{i} u_{k}=u_{j} u_{k} u_{i}, i<j \leq k, \quad(-1)^{p(i) p(k)} q_{k} u_{i} u_{k} u_{j}=u_{k} u_{i} u_{j}, i \leq j<k$.
We define

- deformed/quantum superplactic algebra $\mathcal{S Q} \mathcal{P}_{n}$ to be the quotient of the free associative algebra $\mathbb{Q}\left\langle u_{1}, \ldots, u_{n}\right\rangle$ by the two-sided ideal generated by the set of quantum Knuth relations $\left(S P L_{q}\right)$,
- reduced deformed/quantum superplactic algebras $\mathcal{S Q P \mathcal { C } _ { n }}$ and $\mathcal{S Q P} \mathcal{F}_{n, m}$ to be the quotient of the algebra $\mathcal{S Q P}{ }_{n}$ by the two-sided ideals described in Definitions 5.13 and 6.6 correspondingly.

## We state Conjecture

The algebra $\mathcal{S Q P}_{n}$ and the algebras $\mathcal{S Q P C}_{n}$ and $\mathcal{S Q P F}{ }_{n, m}$, are flat deformations of the algebras $\mathcal{P}_{n}, \mathcal{P} \mathcal{C}_{n}$ and $\mathcal{P} \mathcal{F}_{n, m}$ correspondingly.

In fact one can consider more general deformation of the Knuth relations, for example take a set of parameters $\mathbf{Q}:=\left\{q_{i k}, \quad 1 \leq i<k \leq n\right\}$ and impose on the set of generators $\left\{u_{1}, \ldots, u_{n}\right\}$ the following relations

$$
q_{i k} u_{j} u_{i} u_{k}=u_{j} u_{k} u_{i}, i<j \leq k, \quad q_{i k} u_{i} u_{k} u_{j}=u_{k} u_{i} u_{j}, i \leq j<k .
$$

However we don't know how to describe a set of conditions on parameters $\mathbf{Q}$ which imply the flatness of the corresponding quotient algebra(s), as well as we don't know an interpretation
and dimension of the algebras $\mathcal{S Q P C}_{n}$ and $\mathcal{S Q P \mathcal { P }}{ }_{n, m}$ for a "generic" values of parameters Q. We expect the dimension of algebras $\mathcal{S Q P \mathcal { C }}{ }_{n}$ and $\mathcal{S Q P \mathcal { F } _ { n , m }}$ each depends piece-wise polynomially on a set of parameters $\left\{q_{i j} \in \mathbb{Z}_{\geq 0}, 1 \leq i<j \leq n\right\}$, and pose a problem to describe its polynomiality chambers.

We also mention and leave for a separate publication(s), the case of algebras and polynomials associated with superplactic monoid [44, [27], which corresponds to the relations $S P L_{q}$ with $q_{i}=1, \forall i$. Finally we point out on interesting and important paper 43] wherein the case $Z=\emptyset$, and the all deformation parameters are equal to each other., has been independently introduced and studied in depth.

Let us repeat that the important property of plactic algebras $\mathcal{P}_{n}$ is that the noncommutative elementary polynomials

$$
e_{k}\left(u_{1}, \ldots, n_{n-1}\right):=\sum_{n-1 \geq a_{1} \geq a_{2} \geq a_{k} \geq 1} u_{a_{1}} \cdots u_{a_{k}}, \quad k=1, \ldots, n-1
$$

generate a commutative subalgebra inside of the plactic algebra $\mathcal{P}_{n}$, see e.g. [28], [7]. Therefore the all our finite dimensional algebras introduced in the present paper, have a distinguish finite dimensional commutative subalgebra. We have in mined to describe this algebras explicitly in a separate publication.

In Section 2 we state and prove necessary and sufficient conditions in order the elementary noncommutative polynomials form a mutually commuting family. Surprisingly enough to check the commutativity of noncommutative elementary polynomials for any $n$, it's enough to check these conditions only for $n=2,3$. However a combinatorial meaning of a generalization of the Lascoux-Schützenberger plactic algebra $\mathcal{P}_{n}$ invented, is still missing.

The plactic algebra $\mathcal{P} \mathcal{F}_{n, m}$ introduced in Section 6, has a monomial basis parametrized by the set of Young tableaux of shape $\lambda \subset\left(n^{m}\right)$ filled by the numbers from the set $\{1, \ldots, m\}$. In the case $n=m$ it is well-known [14], [25], [45], that this number is equal to the number of symmetric plane partitions fit inside the cube $n \times n \times n$. Surprisingly enough this number admits a factorization in the product of the number of totally symmetric plane partitions $(T S P P)$ by the number of totally symmetric self-complementary plane partitions(TSSCPP) fit inside the same cube. A similar phenomenon happens if $|m-n| \leq 2$, see Section 6. More precisely, we add to the well-known equalities

- $\#\left|B_{1, n}\right|=2^{n}, \quad \#\left|B_{2, n}\right|=\binom{2 n+1}{n}, \quad \#\left|B_{3, n}\right|=2^{n} C a t_{n}$, [55], A003645, $\#\left|B_{4, n}\right|=\frac{1}{2} C a t_{n} C a t_{n+1}$, [55], A000356, $\#\left|B_{5, n}\right|=\frac{\binom{n+5}{5}\binom{n+7}{7}\binom{n+9}{9}}{\binom{n+2}{2}\binom{n+4}{4}}$, [55], A133348, the following relations
- $\#\left|B_{n, n}=\operatorname{TSPP}(n) \times \operatorname{ASM}(n), \#\right| B_{n, n+1}=\operatorname{TSPP}(n) \times \operatorname{ASM}(n+1)$,
- $\#\left|B_{n+2, n}=\#\right| B_{n, n+1}, \#\left|B_{n+3, n}=\frac{1}{2} \#\right| B_{n+1, n+1}$,
- $\#|P P(n)|=T S P P(n) \times \operatorname{ASMHT}(2 n)=\operatorname{CSSCPP}(2 n) \times \operatorname{CSPP}(n)$,
where $A M S H T(2 n)$ denotes the number of alternating sign matrices of size $2 n \times 2 n$ invariant under a half-turn and $\operatorname{CSSPP}(2 n)$ denotes the set of cyclically symmetric selfcomplementary plane partitions in the $2 n$-cube.
It is well-known that $\operatorname{ASMHT}(2 n)=A S M(n) \times \operatorname{CSPP}(n)$, where $\operatorname{CSPP}(n)$ denotes the number of cyclically symmetric plane partitions in $n$-cube, and $\operatorname{CSSCPP}(2 n)=A S M(n)^{2}$, see e.g. [3], [26], [55], $A 006366$.

## Problem 1.1

- Construct bijection between the set of plane partitions fit inside n-cube and the set of (ordered) triples $\left(\pi_{1}, \pi_{2}, \wp\right)$, where $\left(\pi_{1}, \pi_{2}\right)$ is a pair of $\operatorname{TSSCPP}(n)$ and $\wp$ is a cyclically symmetric plane partition fit inside $n$-cube.
- Describe the involution $\kappa: P P(n) \longrightarrow P P(n)$ which is induced by the involution $\left(\pi_{1}, \pi_{2}, w p\right) \longrightarrow\left(\pi_{2}, \pi_{1}, \wp\right)$ on the set $\operatorname{TSSCPP}(n) \times \operatorname{TSSCP}(n) \times \operatorname{CSPP}(n)$, and its fixed points. Clearly one has \#Fix $(\kappa) \mid=\operatorname{ASMHT}(2 n)$.
- Characterize pairs of plane partitions $\left(\Pi_{1}, \Pi_{2}\right) \in P P(n) \times P P(n)$ such that (a) $\wp\left(\Pi_{1}\right)=\wp\left(\Pi_{2}\right) ; \quad(b) \quad\left(\pi_{1}\left(\Pi_{1}\right), \pi_{2}\left(\Pi_{1}\right)\right)=\left(\pi_{1}\left(\Pi_{2}\right), \pi_{2}\left(\Pi_{2}\right)\right)$.

These relations have strait forward proofs based on the explicit product formulas for the numbers

$$
S P P(n)=\prod_{1 \leq i \leq j \leq k} \frac{n+i+j+k-1}{i+j+k-1} \text { and } T S P P(n)=\prod_{i=1}^{n} \prod_{j=i}^{n} \prod_{k=j}^{n} \frac{i+j+k-1}{i+j+k-2},
$$

but bijective proofs of these identities are an open problem.
It follows from [28], [38] that the dimension of the (reduced) plactic algebra $\mathcal{P C}_{n}$ is equal to the number of alternating sign matrices of size $n \times n(A S M(n)=\operatorname{TSSCPP}(n))$. Therefore the Key-Grothendieck polynomials can be obtained from $U$-polynomials (see Section 6, Theorem 6.9) after the specialization $p_{i j}=0$, if $i+j>n+1$.

In Section 4 follow [20] we introduce and study a family of polynomials which are common generalization of the Schubert, $\beta$-Grothendieck, duel $\beta$-Grothendieck, $(\beta)$-Demazur, $\beta$-KeyGrothendieck, Bott- Samelson and $q$-Demazure polynomials, Whittaker functions (see 4] and Lemma 4.18) and Di-Francesco-Zin-Justin polynomials,(see Section 4). Namely, for any permutation $w \in \mathbb{S}_{n}$ and composition $\zeta \subset \delta_{n}$, we introduce polynomials

$$
\mathcal{K N}_{w}^{(\beta, \alpha, \gamma, h)}\left(X_{n}\right)=h^{\ell(w)} T_{s_{i_{1}}} \cdots T_{s_{i_{\ell}}}\left(x^{\delta_{n}}\right), \quad K D_{\zeta}^{(\beta, \alpha, \gamma, h)}\left(X_{n}\right)=h^{\ell\left(v_{\zeta}\right)} T_{s_{i_{1}}} \cdots T_{s_{i_{\ell}}}\left(x^{\zeta^{+}}\right),
$$

where $\quad T_{i}:=T_{i}^{(\beta, \alpha, \gamma, h)}=$

$$
-\alpha+\left((\alpha+\beta+\gamma) x_{i}+\gamma x_{i+1}+h+h^{-1}(\alpha+\gamma)(\beta+\gamma) x_{i} x_{i+1}\right) \partial_{i, i+1}, \quad i=1, \ldots, n-1
$$

denote a collection of divided difference operators which satisfy the Coxeter and Hecke relations

$$
T_{i} T_{j} T_{i}=T_{j} T_{i} T_{j}, \quad \text { if } \quad|i-j|=1 ; \quad T_{i} T_{j}=T_{j} T_{i}, \quad \text { if } \quad|i-j| \geq 2,
$$

$$
T_{i}^{2}=(\beta-\alpha) T_{i}+\beta \alpha, \quad i=1, \ldots, n-1
$$

by definition we set

$$
T_{w}:=T_{s_{i_{1}}} \cdots T_{s_{i_{\ell}}},
$$

for any reduced decomposition $w=s_{i_{1}} \cdots s_{i_{\ell}}$ of a permutation in question; $\zeta^{+}$denotes a unique partition obtained from $\zeta$ by ordering its parts, and $v_{\zeta} \in \mathbb{S}_{n}$ denotes the minimal length permutation such that $v_{\zeta}(\zeta)=\zeta^{+}$.

Assume that $h=13^{4}$. If $\alpha=\gamma=0$, these polynomials coincide with the $\beta$-Grothendieck polynomials [8], if $\beta=\alpha=1, \gamma=0$ these polynomials coincide with the Di Francesco-ZinJustin polynomials [12], if $\beta=\gamma=0$, these polynomials coincide with dual $\alpha$-Grothendieck polynomials $\mathcal{H}_{w}^{\alpha}(X)$.

Conjecture 1.2 For any permutation $w \in \mathbb{S}_{n}$ and any composition $\zeta \subset \delta_{n}$, polynomials $\mathcal{K} \mathcal{N}_{w}^{(\beta, \alpha, \gamma, h)}\left(X_{n}\right)$ and $K D_{\zeta}^{(\alpha, b e t a, \gamma, h)}\left(X_{n}\right)$ have nonnegative coefficients, i.e.

$$
\mathcal{K} \mathcal{N}_{w}^{(\beta, \alpha, \gamma, h)}\left(X_{n}\right) \in \mathbb{N}[\alpha, \beta, \gamma, h]\left[X_{n}\right], \quad K D_{\zeta}^{(\beta, \alpha, \gamma, h)}\left(X_{n}\right) \in \mathbb{N}[\alpha, \beta, \gamma, h]\left[X_{n}\right]
$$

We expect that these polynomials have some geometrical meaning to be discovered.
More generally we study divided difference type operators of the form

$$
T_{i j}:=T_{i j}^{(a, b, c, d, h, e)}=a+\left(b x_{i}+c x_{j}+h+e x_{i} x_{j}\right) \partial_{i j}
$$

depending on parameters $a, b, c, h, e$ and satisfying the $2 D$-Coxeter relations

$$
T_{i j} T_{j k} T_{i j}=T_{j k} T_{i j} T_{j k}, \quad 1 \leq i<j<k \leq n, \quad T_{i j} T_{k l}=T_{k l} T_{i j}, \text { if } \quad\{i, j\} \cap\{k, l\}=\emptyset .
$$

We find that the necessary and sufficient condition which ensure the validity of the $2 D$ Coxeter relations is the following relation among the parameters:

$$
(\mathrm{a}+\mathrm{b})(\mathrm{a}-\mathrm{c})+\mathrm{he}=0 .
$$

Therefore, if the above relation between parameters $a, b, c, d, h, e$ hold, the the for any permutation $w \in \mathbb{S}_{n}$ the operator

$$
T_{w}:=T_{w}^{(a, b, c, d, h, e)}=T_{i_{1}}^{(a, b, c, d, h, e)} \cdots T_{i_{\ell}}^{(a, b, c, d, h, e)}
$$

where $w=s_{i_{1}} \cdots s_{i_{\ell}}$ is any reduced decomposition of $w$, is well-defined. Hence under the same assumption on parameters, for any permutation $w \in \mathbb{S}_{n}$ one can attach the well-defined polynomial

[^2]and in much the same fashion to define polynomials
$$
D_{\alpha}^{(a, b, c, d, h, e)}(X, Y):=T_{w_{\alpha}}^{(x)^{(a, b, c, d, e)}}\left(x^{\alpha^{+}}\right)
$$
for any composition $\alpha$ such that $\alpha_{i} \leq n-i, \forall i$. We have used the notation $T^{(x)}{ }_{w}^{(a, b, c, d, h, e)}$ to point out that this operator acts only on the variables $X=\left(x_{1}, \ldots, x_{n}\right)$; for any composition $\alpha \in \mathbb{Z}_{\geq 0}^{n}, \alpha^{+}$denotes a unique partition obtained from $\alpha$ by reordering its parts in (weakly) decreasing order, and $w_{\alpha}$ denotes a unique minimal length permutation in the symmetric group $\mathbb{S}_{n}$ such that $w_{\alpha}(\alpha)=\alpha^{+}$.

In the present paper we are interested in to list a conditions on parameters $A:=$ $\{a, b, c, d, h, e\}$ with the constraint

$$
(a+b)(a-c)+h e=0,
$$

which ensure that the above polynomials $G_{w}^{(a, b, c, d, h, e)}(X)$ and $D_{\alpha}^{(a, b, c, d, h, e)}(X)$ or their specialization $x_{i}=1, \forall i$, have nonnegative coefficients. We state the following conjectures:

- $\mathcal{K N}_{w}^{(\beta, \alpha, \gamma)}\left(X_{n}\right) \in \mathbb{N}[\alpha, \beta, \gamma]\left[X_{n}\right]$,
- $G_{w}^{(-b, a+b+c, c, 1,(b+c)(a+c)}\left(X_{n}\right) \in \mathbb{N}[a, b, c]\left[X_{n}\right]$,
- $G_{w}^{(-b, a+b+c, c+d, 1,(b+c+d)(a+c)}\left(x_{i}=1, \forall i\right) \in \mathbb{N}[a, b, c, d]$, where $a, b, c, d$ are free parameters.

In the present paper we treat the case

$$
A=(-\beta, \beta+\alpha+\gamma, \gamma, 1,(\alpha+\gamma)(\beta+\gamma))
$$

As it was pointed above, in this case polynomials $G_{w}^{A}(X)$ are common generalization of Schubert, $\beta$-Grothendieck and dual $\beta$-Grothendieck, and Di Francesco-Zin-Justin polynomials. We expect a certain c interpretation of the polynomials $G_{w}^{A}$ for general $\beta, \alpha$ and $\gamma$.

As it was pointed out earlier, one of the basic properties of the plactic monoid $\mathcal{P}_{n}$ is that the nonocommutative elementary symmetric polynomials $\left\{e_{k}\left(u_{1}, \ldots, u_{n-1}\right)\right\}_{1 \leq k \leq n-1}$ generate a commutative subalgebra in the plactic algebra in question. One can reformulate this statement as follows. Consider the generating function

$$
A_{i}(x) ;=\prod_{a=n-1}^{i}\left(1+x u_{a}\right)=\sum_{a=0}^{i} e_{a}\left(u_{n-1}, \ldots, u_{i}\right) x^{i-a}
$$

where we set $e_{0}(U)=1$. Then the commutativity property of noncommutative elementary symmetric polynomials is equivalent to the following commutativity relation in the plactic as well as in the generic plactic, algebras $\mathcal{P}_{n}$ and $\mathfrak{P}_{n}$, [7], and Theorem 2.23,

$$
A_{i}(x) A_{i}(y)=A_{i}(y) A_{i}(x), \quad 1 \leq i \leq n-1
$$

Now let us consider the Cauchy kernel

$$
\mathcal{C}\left(\mathfrak{P}_{n}, U\right)=A_{1}\left(z_{1}\right) \cdots A_{n-1}\left(z_{n-1}\right),
$$

where we assume that the pairwise commuting variables $z_{1}, \ldots, z_{n-1}$ commute with the all generators of the algebras $\mathcal{P}_{n}$ and $\mathfrak{P}_{n}$. In what follows we consider the natural completion $\widehat{\mathfrak{P}}_{n}$ of the plactic algebra $\mathfrak{P}_{n}$ to allow consider elements of the form $\left(1+x u_{i}\right)^{-1}$. Elements of this form exist in any Hecke type quotient of the plactic algebra $\widetilde{\mathfrak{P}}_{n}$. Having in mind this assumption, let us compute the action of divided difference operators $\partial_{i, i+1}^{z}$ on the Cauchy kernel. In the computation below, the commutativity property of the elements $A_{i}(x)$ and $A_{i}(y)$ plays the key role. Let us start computation of $\partial_{i, i+1}^{z}\left(\mathcal{C}\left(\mathfrak{P}_{n}, U\right)\right)=\partial_{i, i+1}^{z}\left(A_{1}\left(z_{1}\right) \cdots A_{n-1}\left(z_{n-1}\right)\right)$. First of all write $A_{i+1}\left(z_{i+1}\right)=A_{i}\left(z_{i+1}\right)\left(1+z_{i+1} u_{i}\right)^{-1}$. According to the basic property of the elements $A_{i}(x)$, one sees that the expression $A_{i}\left(z_{i}\right) A_{i}\left(z_{i+1}\right)$ is symmetric with respect to $z_{i}$ and $z_{i+1}$, and hence is invariant under the action of divided difference operator $\partial_{i, i+1}^{z}$ Therefore.

$$
\partial_{i, i+1}^{z}\left(\mathcal{C}\left(\mathfrak{P}_{n}, U\right)\right)=A_{1}\left(z_{1}\right) \cdots A_{i}\left(z_{i}\right) A_{i}\left(z_{i+1}\right) \partial_{i, i+1}^{z}\left(\left(1+z_{i+1} u_{i}\right)^{-1}\right) A_{i+2}\left(z_{i+2}\right) \cdots A_{n-1}\left(z_{n-1}\right) .
$$

It is clearly seen that $\left.\partial_{i, i+1}^{z}\left(\left(1+z_{i+1} u_{i}\right)^{-1}\right)=\left(1+z_{i} u_{i}\right)^{-1}\right)\left(1+z_{i+1} u_{i}\right)^{-1} u_{i}$. Therefore

$$
\partial_{i, i+1}^{z}\left(\mathcal{C}\left(\mathfrak{P}_{n}, U\right)\right)=A_{1}\left(z_{1}\right) \cdots A_{i}\left(z_{i}\right) A_{i+1}\left(z_{i+1}\right)\left(1+z_{i} u_{i}\right)^{-1} u_{i} A_{i+2}\left(z_{i+2}\right) \cdots A_{n-1}\left(z_{n-1}\right)
$$

It is easy to see that if one adds Hecke's type relations on the generators

$$
u_{i}^{2}=(a+b) u_{i}+a b, \quad i=1, \ldots, n-1,
$$

then

$$
\left(1+z u_{i}\right)^{-1} u_{i}=\frac{u_{i}-z a b}{(1+b z)(1-a z)}
$$

Therefore in the quotient of the plactic algebra $\mathfrak{P}_{n}$ by the Hecke type relations listed above and by the "locality" relations

$$
u_{i} u_{j}=u_{j} u_{i}, \quad \text { if } \quad|i-j| \geq 2
$$

one obtains

$$
\left(-b+\left(1+z_{i} b\right)\right) \partial_{i, i+1}^{z}\left(A_{1}\left(z_{1}\right) \cdots A_{n-1}\left(z_{n-1}\right)\right)=\left(A_{1}\left(z_{1}\right) \cdots A_{n-1}\left(z_{n-1}\right)\right)\left(\frac{e_{i}-b}{1-a z_{i}}\right)
$$

Finally, if $a=0$, then the above identity takes the following form

$$
\partial_{i, i+1}^{z}\left(\left(1+z_{i+1} b\right) A_{1}\left(z_{1}\right) \cdots A_{n-1}\left(z_{n-1}\right)\right)=\left(A_{1}\left(z_{1}\right) \cdots A_{n-1}\left(z_{n-1}\right)\right)\left(e_{i}-b\right)
$$

In other words the above identity is equivalent to the statement 9] that in the IdCoxeter algebra $\mathcal{I C}_{n}$ the Cauchy kernel $\mathcal{C}\left(\mathfrak{P}_{n}, U\right)$ is the generating function for the $b$-Grothendieck polynomials. Moire over, each (generalized) double $b$-Grothendieck polynomial is a positive linear combination of the key- Grothendieck polynomials. In the special case $b=-1$ and $P_{i j}=$ $x_{i}+y_{j}$ if $2 \leq i+j \leq n+1, \quad p_{i j}=0$, if $i+j>n+1$ this result had been stated in [39].

As a possible mean to define affine versions of polynomials treated in the present paper, we introduce the double affine nilCoxeter algebra of type $A$ and give construction of a generic family of Hecke's type elements 5 we will be put to use in the present paper.

As Appendix we include several examples of polynomials studied in the present paper to illustrate results obtained in these notes. We also include an expository text concerning the MacNeille completion of a poset to draw attention of the reader to this subject. It is the MacNeille completion of the poset associated with the (strong) Bruhat order on the symmetric group, that was one of the main streams of the study in the present paper.

A bit of history. Originally these notes have been designed as a continuation of [8]. The main purpose was to extend the methods developed in 10 to obtain by the use of plactic algebra, a noncommutative generating function for the key (or Demazure) polynomials introduced by A. Lascoux and M.-P. Schützenberger [34]. The results concerning the polynomials introduced in Section 4, except the Hecke- Grothendieck polynomials, see Definition 4.6, has been presented in my lecture-courses "Schubert Calculus" have been delivered in the Graduate School of Mathematical Sciences, the University of Tokyo, November 1995 -April 1996, and in the Graduate School of Mathematics, Nagoya University, October 1998 - April 1999. I want to thank Professor M. Noumi and Professor T. Nakanishi who made these courses possible. Some early versions of the present notes are circulated around the world and now I was asked to put it for the wide audience. I would like to thank Professor M. Ishikawa (Department of Mathematics, Faculty of Education, University of the Ryukyus, Okinawa, Japan) and Professor S.Okada (Graduate School of Mathematics, Nagoya University, Nagoya, Japan) for valuable comments.

## 2 Plactic, nilplactic and idplactic algebras

Definition 2.1 ([28]) The plactic algebra $\mathcal{P}_{n}$ is an (unital) associative algebra over $\mathbb{Z}$ generated by elements $\left\{u_{1}, \cdots, u_{n-1}\right\}$ subject to the set of relations
(PL1) $\quad u_{j} u_{i} u_{k}=u_{j} u_{k} u_{i}, \quad u_{i} u_{k} u_{j}=u_{k} u_{i} u_{j}$, if $i<j<k$,
(PL2) $\quad u_{i} u_{j} u_{i}=u_{j} u_{i} u_{i}, \quad u_{j} u_{i} u_{j}=u_{j} u_{j} u_{i}$, if $i<j$.
Proposition 2.2 ([28])Tableau words in the alphabet $U=\left\{u_{1}, \cdots, u_{n-1}\right\}$ form a basis in the plactic algebra $\mathcal{P}_{n}$.

In other words, each plactic class contain a unique tableau word. In particular,

$$
\operatorname{Hilb}\left(\mathcal{P}_{n}, t\right)=(1-t)^{-n}\left(1-t^{2}\right)^{-\binom{n}{2}} .
$$

[^3]Remark 2.3 There exists another algebra over $\mathbb{Z}$ which has the same Hilbert series as that of the plactic algebra $\mathcal{P}_{n}$. Namely, define algebra $\mathcal{L}_{n}$ to be an associative algebra over $\mathbb{Z}$ generated by the elements $\left\{e_{1}, e_{2}, \ldots, e_{n-1}\right\}$, subject to the set of relations

$$
\left(e_{i},\left(e_{j}, e_{k}\right)\right):=e_{i} e_{j} e_{k}-e_{j} e_{i} e_{k}-e_{j} e_{k} e_{i}+e_{k} e_{j} e_{i}=0, \quad \text { for all } 1 \leq i, j, k \leq n-1, \quad j<k .
$$

Note that the number of defining relations in the algebra $\mathcal{L}_{n}$ is equal to $2\binom{n}{3}$.
One can show that the dimension of the degree $k$ homogeneous component $\mathcal{L}_{n}^{(k)}$ of the algebra $\mathcal{L}_{n}$ is equal to the number semistandard Young tableaux of the size $k$ filled by the numbers from the set $\{1,2, \ldots, n\}$.

Definition 2.4 The local plactic algebra $\mathcal{L P}{ }_{n}$ is an associative algebra over $\mathbb{Z}$ generated by elements $\left\{u_{1}, \ldots, u_{n-1}\right\}$ subject to the set of relations

$$
u_{i} u_{j}=u_{j} u_{i}, \quad \text { if } \quad|i-j| \geq 2, \quad u_{j} u_{i}^{2}=u_{i} u_{j} u_{i}, \quad u_{j}^{2} u_{i}=u_{j} u_{i} u_{j}, \quad \text { if } \quad j=i+1 .
$$

One can show (A.K) that

$$
\operatorname{Hilb}\left(\mathcal{L} \mathcal{P}_{n}, t\right)=\prod_{j=1}^{n}\left(\frac{1}{1-t^{j}}\right)^{n+1-j}
$$

## Definition 2.5 (Nil Temperley-Lieb algebra)

Denote by $\mathcal{T} \mathcal{L}_{n}^{(0)}$ the quotient of the local plactic algebra $\mathcal{L P}{ }_{n}$ by the two-sided ideal generated by the elements $\left\{u_{1}^{2}, \ldots, u_{n-1}^{2}\right\}$.

It is well-known that $\operatorname{dim} \mathcal{T} \mathcal{L}_{n}=C_{n}$, the $n$-th Catalan number. One also has
$\operatorname{Hilb}\left(\mathcal{T} \mathcal{L}_{4}^{(0)}, t\right)=(1,3,5,4,1), \quad \operatorname{Hilb}\left(\mathcal{T} \mathcal{L}_{5}^{(0)}, t\right)=(1,4,9,12,10,4,2)$,
$\operatorname{Hilb}\left(\mathcal{T} \mathcal{L}_{6}^{(0)}, t\right)=(1,5,14,25,31,26,16,9,4,1)$.

## Proposition 2.6

The Hilbert polynomial $\operatorname{Hilb}\left(\mathcal{T} \mathcal{L}_{n}^{(0)}, t\right)$ is equal to the generating function for the number of 321 -avoiding permutations of the set $\{1,2, \ldots, n\}$ having inversion number equal to $k$, see [55], A140717, for other combinatorial interpretations of polynomials $\operatorname{Hilb}\left(\mathcal{T} \mathcal{L}_{n}^{(0)}, t\right)$.

We denote by $\mathcal{T} \mathcal{L}_{n}^{(\beta)}$ the quotient of the local plactic algebra $\mathcal{L} \mathcal{P}_{n}$ by the two-sided ideal generated by the elements $\left\{u_{1}^{2}-\beta u_{1}, \ldots, u_{n-1}^{2}-\beta u_{n-1}\right\}$.

Definition 2.7 The modified plactic algebra $\mathcal{M} \mathcal{P}_{n}$ is an associative algebra over $\mathbb{Z}$ generated by $\left\{u_{1}, \ldots, u_{n-1}\right\}$ subject to the set of relations (PL1) and that

$$
u_{j} u_{j} u_{i}=u_{j} u_{i} u_{i} \quad \text { and } \quad u_{i} u_{j} u_{i}=u_{j} u_{i} u_{j}, \quad \text { if } \quad 1 \leq i<j \leq n-1 .
$$

Definition 2.8 The (reduced) nilplactic algebra $\mathcal{N} \mathcal{P}_{n}$ is an associative algebra over $\mathbb{Q}$ generated by $\left\{u_{1}, \cdots, u_{n-1}\right\}$ subject to the relations ${ }^{6}$

$$
\begin{equation*}
u_{i}^{2}=0, \quad u_{i} u_{i+1} \quad u_{i}=u_{i+1} u_{i} u_{i+1} \tag{2.4}
\end{equation*}
$$

the set of relations (PL1), and that $\quad x_{i} x_{j} x_{i}=0$, if $|i-j| \geq 2$.
Proposition 2.9 ([32]) Each nilplactic class not containing 0, contains one and only one tableau word.

Proposition 2.10 The nilplactic algebra $\mathcal{N}^{( } \mathcal{P}_{n}$ has finite
dimension, its Hilbert polynomial $\operatorname{Hilb}\left(\mathcal{N} \mathcal{P}_{n}, t\right)$ has degree $\binom{n}{2} \quad$ and $\operatorname{dim}\left(\mathcal{N} \mathcal{P}_{n}\right)_{\binom{n}{2}}=1$.
Example 2.11 $\operatorname{Hilb}\left(\mathcal{N P}_{3}, t\right)=(1,2,2,1), \quad \operatorname{Hilb}\left(\mathcal{N} \mathcal{P}_{4}, t\right)=(1,3,6,6,5,3,1)$, $\operatorname{Hilb}\left(\mathcal{N} \mathcal{P}_{5}, t\right)=(1,4,12,19,26,26,22,15,9,4,1), \operatorname{dim}\left(\mathcal{N} \mathcal{P}_{5}=139\right.$, $\operatorname{Hilb}\left(\mathcal{N} \mathcal{P}_{6}, t\right)=(1,5,20,44,84,119,147,152,140,114,81,52,29,14,5,1), \operatorname{dim}\left(\mathcal{N} \mathcal{P}_{6}\right)=1008$.

Definition 2.12 The idplactic algebra $\mathcal{I P}_{n}^{(\beta)}$ is an associative algebra over $\mathbb{Q}(\beta)$ generated by $\left\{u_{1}, \cdots, u_{n-1}\right\}$ subject to the relations

$$
\begin{equation*}
u_{i}^{2}=\beta u_{i}, \quad u_{i} u_{j} u_{i}=u_{j} u_{i} u_{j}, \quad i<j, \tag{2.5}
\end{equation*}
$$

and the set of relations (PL1).
In other words, the idplactic algebra $\mathcal{I P}{ }_{n}$ is the quotient of the plactic algebra $\mathcal{P}_{n}$ by the the two-sided ideal generated by elements $\left\{u_{i}^{2}-\beta u_{i}, \quad 1 \leq i \leq n-1\right\}$.

Proposition 2.13 Each idlplactic class contains a unique tableau word of the smallest length.

For each word $w$ denote by $r l(w)$ the length of a unique tableau word of minimal length which is idplactic equivalent to $w$.
${ }^{6}$ Original definition of the nilplactic relations given in 32] involves only relations (PL1) and

$$
u_{i} u_{i+1} u_{i} \cong u_{i+1} u_{i} u_{i+1} \quad \& \quad u_{i} u_{i} \cong 0, \quad i=1, \ldots, n-1 .
$$

It had been shown [33] that the Schensted construction for the plactic congruence extends to the nilplactic case. However as it seen from the following example, as a consequence of relations ( $P L 1$ ) one has

$$
\left(u_{1}+u_{2}+u_{3}, u_{2} u_{1}+u_{3} u_{1}+u_{3} u_{2}\right) \equiv u_{1} u_{3} u_{1}-u_{3} u_{1} u_{3}+u_{3}^{2} u_{1}-u_{3} u_{1}^{2}
$$

and therefore noncommutative elementary symmetric polynomials $e_{1}\left(u_{1}, u_{2}, u_{3}\right)$ and $e_{2}\left(\left(u_{1}, u_{2}, u_{3}\right)\right.$ do not commute modulo the nilplactic congruence defined in 32 . Indeed, $u_{1} u_{3} u_{1} \not \equiv u_{3} u_{1} u_{3}$. In order to guarantee the commutativity of all noncommutative elementary polynomials, we add relations

$$
x_{i} x_{j} x_{i}=0, \quad \text { if } \quad|i-j| \geq 2
$$

Cf with definition of idplactic relations listed in Definition 2.11.

Example 2.14 Consider words in the alphabet $\{a<b<c<d\}$. Then
$r l(d b a d c)=4=r l(c a d b d), \quad r l(d b a d b c)=5=r l(c b a d b d) . \quad$ Indeed,

$$
d b a d c \sim d b d a c \sim d b d c a \sim d d b c a \sim d b a c,
$$

$$
d b a d b c \sim d b a b d c \sim d a b a d c \sim a d b d a c \sim a b d b c a \sim a b b d c a \sim d b a b c
$$

Note that according to our definition, tableau words $w=31, w=13$ and $w=313$ belong to different idplactic classes.

Proposition 2.15 The idplactic algebra $\mathcal{I P}_{n}^{(\beta)}$ has finite dimension, and its Hilbert polynomial has degree $\binom{n}{2}$.

## Example 2.16

$\operatorname{Hilb}\left(\mathcal{I P}_{3}, t\right)=(1,2,2,1), \operatorname{Hilb}\left(\mathcal{I} \mathcal{P}_{4}, t\right)=(1,3,6,7,5,3,1), \operatorname{dim}\left(\mathcal{I} \mathcal{P}_{4}\right)=26$, $\operatorname{Hilb}\left(\mathcal{I P}_{5}, t\right)=(1,4,12,22,30,32,24,15,9,4,1), \operatorname{dim}\left(\mathcal{I} \mathcal{P}_{5}\right)=154$,
$\operatorname{Hilb}\left(\mathcal{I} \mathcal{P}_{6}, t\right)=(1,5,20,50,100,156,188,193,173,126,84,52,29,14,5,1), \quad \operatorname{dim}\left(\mathcal{I} \mathcal{P}_{6}\right)=1197$.
Definition 2.17 The idplactic Temperly-Lieb algebra $\mathcal{P} \mathcal{T} \mathcal{L}_{n}^{(\beta)}$ is define to be the quotient of the idplactic algebra $\mathcal{I} \mathcal{P}_{n}^{(\beta)}$ by the two-sided ideal generated by the elements

$$
\left\{u_{i} u_{j} u_{i}, \quad \forall i \neq j\right\} .
$$

For example, $\quad \operatorname{Hilb}\left(\mathcal{P} \mathcal{T} \mathcal{L}_{4}^{(0)}, t\right)=(1,3,6,4,1)_{t}, \quad \operatorname{Hilb}\left(\mathcal{P} \mathcal{T} \mathcal{L}_{5}^{(0)}, t\right)=(1,4,12,16,14,4,2)_{t}$ $\operatorname{Hilb}\left(\mathcal{P} \mathcal{T} \mathcal{L}_{6}^{(0)}, t\right)=(1,5,20,40,60,46,32,10,4,1)_{t}, \quad \operatorname{Hilb}\left(\mathcal{P} \mathcal{T} \mathcal{L}_{7}^{(0)}, t\right)=$ $(1,6,30,80,170,216,238,152,96,44,14,4,2)_{t} . \quad$ One can show that $\operatorname{deg}_{t} \operatorname{Hilb}\left(\mathcal{P} \mathcal{T} \mathcal{L}_{n}^{(0)}, t\right)=$ $\left[\frac{n^{2}}{4}\right]$, and $\operatorname{Coef} f_{t^{\max }} \operatorname{Hilb}\left(\mathcal{P} \mathcal{T} \mathcal{L}_{n}, t\right)=1$, if $n$ is even, and $=2$, if $n$ is odd.

Definition 2.18 The nilCoxeter algebra $\mathcal{N C}_{n}$ is defined to be the quotient of the nilplactic algebra $\quad \mathcal{N} \mathcal{P}_{n}$ by the two-sided ideal generated by elements $\left\{u_{i} u_{j}-u_{j} u_{i}, \quad|i-j| \geq 2\right\}$.

Clearly the nilCoxeter algebra $\mathcal{N C}_{n}$ is a quotient of the modified plactic algebra $\mathcal{M} \mathcal{P}_{n}$ by the two-sided ideal generated by the elements $\left\{u_{i} u_{j}-u_{j} u_{i}, \quad|i-j| \geq 2\right\}$.

Definition 2.19 The idCoxeter algebra $\mathcal{I C}_{n}^{(\beta)}$ is defined to be the quotient of the idplactic algebra $\mathcal{I P}_{n}^{(\beta)} \quad$ by the two-sided ideal generated by the elements $\quad\left\{u_{i} u_{j}-\right.$ $\left.u_{j} u_{i}, \quad|i-j| \geq 2\right\}$.

It is well-known that the algebras $\mathcal{N C}_{n}$ and $\mathcal{I C}_{n}^{(\beta)}$ have dimension $n$ !, and the elements $\left\{u_{w}:=u_{i_{1}} \cdots u_{i_{\ell}}\right\}$, where $w=s_{i_{1}} \cdots s_{i_{\ell}}$ is any reduced decomposition of $w \in \mathbb{S}_{n}$, form a basis in the nilCoxeter and idCoxeter algebras $\mathcal{N C} \mathcal{C}_{n}$ and $\mathcal{I C}{ }_{n}^{(\beta)}$.

Remark 2.20 There is a common generalization of the algebras defined above which is due to S.Fomin and C.Greene [7]. Namely, define generalized plactic algebra $\widetilde{\mathcal{P}}_{n}$ to be an associative algebra generated by elements $u_{1}, \cdots, u_{n-1}$, subject to the relations (PL2) and relations

$$
\begin{equation*}
u_{j} u_{i}\left(u_{i}+u_{j}\right)=\left(u_{i}+u_{j}\right) u_{j} u_{i}, \quad i<j . \tag{2.6}
\end{equation*}
$$

The relation (2.5) can be written also in the form

$$
u_{j}\left(u_{i} u_{j}-u_{j} u_{i}\right)=\left(u_{i} u_{j}-u_{j} u_{i}\right) u_{i}, i<j .
$$

Theorem 2.21 ( [7]) For each pair of numbers $1 \leq i<j \leq n$ define

$$
A_{i, j}(x)=\prod_{k=j}^{i}\left(1+x u_{k}\right) .
$$

Then the elements $A_{i, j}(x)$ and $A_{i, j}(y)$ commute in the generalized plactic algebra $\widetilde{\mathcal{P}}_{n}$.
Corollary 2.22 Let $1 \leq i<j \leq n$ be a pair of numbers. Noncommutative elementary polynomials $\quad e_{a}^{i j}:=\sum_{j \geq i_{1} \geq \cdots \geq i_{k} \geq i} u_{i_{1}} \cdots u_{i_{a}}, \quad i \leq a \leq j, \quad$ generate a commutative subalgebra $\mathcal{C}_{i, j}$ of rank $j-i+1$ in the plactic algebra $\mathcal{P}_{n}$.

Moreover, the algebra $\mathcal{C}_{1, n}$ is a maximal commutative subalgebra of $\mathcal{P}_{n}$.
To establish Theorem 2.20 , we are going to prove more general result. To start with, let us define generic plactic algebra $\mathfrak{P}_{n}$.

Definition 2.23 The generic plactic algebra $\mathfrak{P}_{n}$ is an associative algebra over $\mathbb{Z}$ generated by $\quad\left\{e_{1}, \cdots, e_{n-1}\right\}$ subject to the set of relations

$$
\begin{gather*}
e_{j}\left(e_{i}, e_{)}=\left(e_{i}, e_{j}\right) e_{i}, \quad \text { if } i<j\right.  \tag{2.7}\\
\left(e_{j},\left(e_{i}, e_{k}\right)\right)=0, \quad \text { if } \quad i<j<k  \tag{2.8}\\
\left(e_{j}, e_{k}\right)\left(e_{i}, e_{k}\right)=0, \quad \text { if } \quad i<j<k \tag{2.9}
\end{gather*}
$$

Clearly seen that relations (2.6) - (2.8) are consequence of the plactic relations (PL1) and (PL2).
Theorem 2.24 Define

$$
A_{n}(x)=\prod_{k=j}^{1}\left(1+x e_{k}\right)
$$

Then the elements $A_{n}(x)$ and $A_{n}(y)$ commute in the generic plactic algebra $\mathfrak{P}_{n}$.
Moreover the elements $A_{n}(x)$ and $A_{n}(y)$ commute if and only if the generators $\left\{e_{1}, \ldots, e_{n-1}\right\}$ satisfy the relations (2.6) - (2.8).

Proof For $n=2,3$ the statement of Theorem 1.22 is obvious. Now assume that the statement of Theorem 1.22 is true in the algebra $\mathfrak{P}_{n}$. We have to prove that the commutator $\left[A_{n+1}(x), A_{n+1}(y)\right]$ is equal to zero. First of all, $A_{n+1}(x)=\left(1+x e_{n}\right) A_{n}(x)$. Therefore

$$
\left[A_{n+1}(x), A_{n+1}(y)\right]=\left(1+x e_{n}\right)\left[A_{n}(x), 1+y e_{n}\right] A_{n}(y)-\left[A_{n}(y), 1+x e_{n}\right] A_{n}(x)
$$

Using the standard identity $[a b, c]=a[b, c]+[a, c] b$, one finds that

$$
\frac{1}{x y}\left[A_{n}(x), 1+y e_{n}\right]=\sum_{i=}^{n-1} \prod_{a=n-1}^{i+1}\left(1+x e_{a}\right)\left(e_{i}, e_{n}\right) \prod_{a=i-1}^{1}\left(1+x e_{a}\right)
$$

Using relations (2.7) we can move the commutator $\left(e_{i}, e_{n}\right)$ to the left, since $i<a<n$, till we meet the term $\left(1+x e_{n}\right)$. Using relations (2.6) we see that $\left(1+x e_{n}\right)\left(e_{i}, n\right)=\left(e_{i}, n\right)\left(1+x e_{i}\right)$. Therefore we come to the following relation

$$
\begin{gathered}
\frac{1}{x y}\left[A_{n}(x), 1+y e_{n}\right]= \\
\sum_{i=n-1}^{1}\left(e_{i}, e_{n}\right)\left(\left(1+x e_{i}\right) \prod_{\substack{a=n-1 \\
a \neq i}}^{1}\left(1+x e_{a}\right) A_{n}(y)-\left(1+y e_{i}\right) \prod_{\substack{a=n-1 \\
a \neq i}}^{1}\left(1+y e_{a}\right) A_{n}(x)\right) .
\end{gathered}
$$

Finally let us observe that
$\left(e_{i}, e_{n}\right)\left(\left(1+x e_{i}\right)\left(1+x e_{n-1}\right)-\left(1+x e_{n-1}\right)\left(1+x e_{i}\right)\right)=x^{2}\left(e_{i}, e_{n}\right)\left(e_{i}, e_{n-1}\right)=0$, according to (2.8).
Indeed, $\left(e_{i}, e_{n}\right)\left(e_{i}, e_{n-1}\right)=\left(e_{i}, e_{n}\right) e_{i} e_{n-1}-\left(e_{i}, e_{n}\right) e_{n-1} e_{i}=e_{n} e_{n-1}\left(e_{i}, e_{n}\right)-e_{n-1} e_{n}\left(e_{i}, e_{n}\right)=$ 0 . Therefore $\frac{1}{x y}\left[A_{n}(x), 1+y e_{n}\right]=\left(\sum_{i=n-1}^{1}\left(e_{i}, e_{n}\right)\right)\left[A_{n}(x), A_{n}(y)\right]=0$ according to the induction assumption.

Finally, if $i<j$, then $\left(e_{i}+e_{j}, e_{j} e_{i}\right)=0 \Longleftrightarrow(2.6)$,
if $i<j<k$ and the relations (2.6) hold, then $\left(e_{i}+e_{j}+e_{k}, e_{j} e_{i}+e_{k} e_{j}+e_{k} e_{i}\right)=0 \Longleftrightarrow(2.7)$, if $i<j<k$ and relations (2.6) and (2.7) hold, then $\left(e_{i}+e_{j}+e_{k}, e_{k} e_{j} e_{i}\right)=0 \Longleftrightarrow(2.8)$; the relations $\left(e_{j} e_{i}+e_{k} e_{j}+e_{k} e_{i}, e_{k} e_{j} e_{i}\right)=0$ are a consequence of the above ones.

Let $T$ be a semistandard tableau and $w(T)$ be the column reading word corresponding to the tableau $T$. Denote by $R(T)$ (resp. $I R(T)$ ) the set of words which are plactic (resp. idplactic) equivalent to $w(T)$. Let $\mathbf{a}=\left(a_{1}, \cdots, a_{n}\right) \in R(T)$, where $n:=|T| \quad$ (resp. $\mathbf{a}=$ $\left(a_{1}, \cdots, a_{m}\right) \in I R(T)$, where $\left.m \geq|T|\right)$.

Definition 2.25 (Compatible sequences $\mathbf{b}$ ) Given a word $\mathbf{a} \in R(T)$ (resp. a $\in I R(T)$ ), denote by $C(\mathbf{a})$ (resp. IC(a)) the set of sequences of positive integers, called compatible sequences, $\mathbf{b}:=\left(b_{1} \leq b_{2} \leq \cdots \leq b_{m}\right)$ such that

$$
\begin{equation*}
b_{i} \leq a_{i}, \quad \text { and } \quad \text { if } \quad a_{i} \leq a_{i+1}, \quad \text { then } \quad b_{i}<b_{i+1} \tag{2.10}
\end{equation*}
$$

Finally, define the set $C(T)$ (resp. $I C(T)$ ) to be the union $\bigcup C(\mathbf{a})$ (resp. the union $\bigcup I C(\mathbf{a})$ ), where a runs over all words which are plactic (resp. idplactic) equivalent to the word $w(T)$.

Example 2.26 Take $T=\begin{array}{ll}2 & 3 \\ 3\end{array}$. The corresponding tableau word is $w(T)=323$. We have $R(T)=\{232,323\}$ and $\operatorname{IR}(T)=R(T) \bigcup\{2323,3223,3232,3233,3323,32323, \cdots\}$. Moreover,

$$
\begin{aligned}
& C(T)=\left\{\begin{array}{llllll}
\mathbf{a}: & 232 & 323 & 323 & 323 & 323 \\
\mathbf{b}: & 122 & 112 & 113 & 123 & 223
\end{array}\right\}, \\
& I C(T)=C(T) \bigcup\left\{\begin{array}{lllllll}
\mathbf{a}: & 2323 & 3223 & 3232 & 3233 & 3323 & 32323 \\
\mathbf{b}: & 1223 & 1123 & 1122 & 1123 & 1223 & 11223
\end{array}\right\} .
\end{aligned}
$$

Let $\mathfrak{P}:=\mathfrak{P}_{n}:=\left\{p_{i, j}, i \geq 1, j \geq 1,2 \leq i+j \leq n+1\right\}$ be the set of (mutually commuting) variables.

Definition 2.27 (1) Let $T$ be a semistandard tableau, and $n:=|T|$. Define the double key polynomial $\mathcal{K}_{T}(\mathfrak{P})$ corresponding to the tableau $T$ to be

$$
\begin{equation*}
\mathcal{K}_{T}(\mathfrak{P})=\sum_{\mathbf{b} \in C(T)} \prod_{i=1}^{n} p_{b_{i}, a_{i}-b_{i}+1} \tag{2.11}
\end{equation*}
$$

(2) Let $T$ be a semistandard tableau, and $n:=|T|$. Define the double key Grothendieck polynomial $\mathcal{G K}_{T}(\mathfrak{P})$ corresponding to the tableau $T$ to be

$$
\begin{equation*}
\mathcal{G K}_{T}(\mathfrak{P})=\sum_{\mathbf{b} \in I C(T)} \prod_{i=1}^{m} p_{b_{i}, a_{i}-b_{i}+1} \tag{2.12}
\end{equation*}
$$

In the case when $p_{i, j}=x_{i}+y_{j}, \forall i, j$, where $X=\left\{x_{1}, \ldots, x_{n}\right\}$ and $Y=\left\{y_{1}, \ldots, y_{n}\right\}$ denote two sets of variables, we will write $\mathcal{K}_{T}(X, Y), \mathcal{G K}_{T}(X, Y), \ldots$, instead of $\mathcal{K}_{T}(\mathfrak{P})$, $\mathcal{G} \mathcal{K}_{T}(\mathfrak{P}), \ldots$

Definition 2.28 Let $T$ be a semistandard tableau, denote by $\alpha(T)=\left(\alpha_{1}, \cdots, \alpha_{n}\right)$ the exponent of the smallest monomial in the set $\left\{x^{\mathbf{b}}:=\prod_{i=1}^{m} x_{i}^{b_{i}}, \mathbf{b} \in C(T)\right\}$ with respect to the lexicographic order.

We will call the composition $\alpha(T)$ to be the bottom code of tableau $T$.

## 3 Divided difference operators

In this subsection we remind some basic properties of divided difference operators will be put to use in subsequent Sections. For more details, see 46].

Let $f$ be a function of the variables $x$ and $y$ (and possibly other variables), and $\eta \neq 0$ be a parameter. Define the divided difference operator $\partial_{x y}(\eta)$ will as follows

$$
\partial_{x y}(\eta) f(x, y)=\frac{f(x, y)-f\left(\eta^{-1} y, \eta x\right)}{x-\eta^{-1} y}
$$

Equivalently, $\quad\left(x-\eta^{-1} y\right) \partial_{x y}(\eta)=1-s_{x y}^{\eta}, \quad$ where the operator $s_{x y}^{\eta}$ acts on the variables $(x, y, \ldots)$ according to the rule: $s_{x y}^{\eta}$ transforms the pair $(x, y)$ to $\left(\eta^{-1} y, \eta x\right)$, and fixes all other variables. We set by definition, $s_{y x}^{\eta}:=s_{x y}^{\eta^{-1}}$.

The operator $\partial_{x y}(\eta)$ takes polynomials to polynomials and has degree -1 . The case $\eta=1$ corresponds to the Newton divided difference operator $\partial_{x y}:=\partial_{x y}(1)$.

Lemma 3.1
(0) $s_{x y}^{\eta} s_{x z}^{\eta \xi}=s_{y z}^{\xi} s_{x y}^{\eta}, \quad s_{x y}^{\eta} s_{x z}^{\eta \xi} s_{y z}^{\xi}=s_{y z}^{\xi} s_{x z}^{\eta \xi} s_{x y}^{\eta}$,
(1) $\partial_{y x}(\eta)=-\eta \partial_{x y}\left(\eta^{-1}\right), \quad s_{x y}^{\eta} \partial_{y z}(\xi)=\eta^{-1} \partial_{x z}(\eta \xi) s_{x y}^{\eta}$,
(2) $\partial_{x y}(\eta)^{2}=0$,
(3) (Three term relation)
$\partial_{x y}(\eta) \partial_{y z}(\xi)=\eta^{-1} \partial_{x z}(\eta \xi) \partial_{x y}(\eta)+\partial_{y z}(\xi) \partial_{x z}(\eta \xi)$.
(4) (Twisted Leibniz rule)
$\partial_{x y}(\eta)(f g)=\partial_{x y}(\eta)(f) g+s_{x y}^{\eta}(f) \partial_{x y}(\eta)(g)$,
(5) (Crossing relations, of [9], (4.6))

- $x \partial_{x y}(\eta)=\eta^{-1} \partial_{x y}(\eta) y+1, \quad y \partial_{x y}(\eta)=\eta \partial_{x y}(\eta) x-\eta$,
- $\partial_{x y}(\eta) y \partial_{y z}(\xi)=\partial_{x z}(\eta \xi) x \partial_{x y}(\eta)+\xi^{-1} \partial_{y z}(\xi) z \partial_{x z}(\eta \xi)$,
(6) $\partial_{x y} \partial_{x z} \partial_{y z} \partial_{x z}=0$.

Let $x_{1}, \ldots, x_{n}$ be independent variables, and let $P_{n}:=\mathbb{Q}\left[x_{1}, \ldots, x_{n}\right]$. For each $i<j$ put $\partial_{i j}:=\partial_{x_{i} x_{j}}(1)$ and $\partial_{j i}=-\partial_{i j}$. From Lemma 2.1 we have

$$
\left\{\begin{array}{c}
\partial_{i j}^{2}=0 \\
\partial_{i j} \partial_{j k}+\partial_{k i} \partial_{i j}+\partial_{j k} \partial_{k i}=0, \\
\partial_{i j} x_{j} \partial_{j k}+\partial_{k i} x_{i} \partial_{i j}+\partial_{j k} x_{k} \partial_{k i}, \quad \text { if } \quad i, j, k \quad \text { are distinct. }
\end{array}\right.
$$

It is interesting to consider also an additive or affine analog $\partial_{x y}[k]$ of the divided difference operators $\partial_{x y}(\eta)$, namely,

$$
\partial_{x y}[k](f(x, y))=\frac{f(x, y)-f(y-k, x+k)}{x-y+k}
$$

We have $\partial_{y x}[k]=-\partial_{x y}[-k]$, and
$\partial_{x y}[p] \partial_{y z}[q]=\partial_{x z}[p+q] \partial_{x y}[p]+\partial_{y z}[q] \partial_{x z}[p+q]$.

## 4 Schubert, Grothendieck and Key polynomials

Let $w \in \mathbb{S}_{n}$ be a permutation, $X=\left(x_{1}, \cdots, x_{n}\right)$ and $Y=\left(y_{1}, \cdots, y_{n}\right)$ be two sets of variables. Denote by $w_{0} \in \mathbb{S}_{n}$ the longest permutation, and by $\delta:=\delta_{n}=(n-1, n-2, \cdots, 1)$ the staircase
partition. For each partition $\lambda$ define

$$
R_{\lambda}(X, Y):=\prod_{(i, j) \in \lambda}\left(x_{i}+y_{j}\right) .
$$

For $i=1, \cdots, n-1$, let $s_{i}=(i, i+1) \in \mathbb{S}_{n}$ denote the simple transposition that interchanges $i$ and $i+1$ and fixes all other elements of the set $\{1, \cdots, n\}$. If $\alpha=\left(\alpha_{1}, \cdots, \alpha_{i}, \alpha_{i+1}, \cdots, \alpha_{n}\right)$ is a composition, we will write

$$
s_{i} \alpha=\left(\alpha_{1}, \cdots, \alpha_{i+1}, \alpha_{i}, \cdots, \alpha_{n}\right)
$$

## Definition 4.1

- For each permutation $w \in \mathbb{S}_{n}$ the double Schubert polynomial $\mathfrak{S}_{w}(X, Y)$ is defined to be

$$
\partial_{w^{-1} w_{0}}^{(x)}\left(R_{\delta_{n}}(X, Y)\right) .
$$

Let $\alpha$ be a composition.

- The key polynomials $K[\alpha](X)$ are defined recursively as follows:
if $\alpha$ is a partition, then $K[\alpha](X)=x^{\alpha}$;
otherwise, if $\alpha$ and $i$ are such that $\alpha_{i}<\alpha_{i+1}$, then

$$
K\left[s_{i}(\alpha)\right](X)=\partial_{i}\left(x_{i} K[\alpha](X)\right)
$$

- The reduced key polynomials $\widehat{K}[\alpha](X)$ are defined recursively as follows:
if $\alpha$ is a partition, then $\widehat{K}[\alpha](X)=K[\alpha](X)=x^{\alpha}$;
otherwise, if $\alpha$ and $i$ are such that $\alpha_{i}<\alpha_{i+1}$, then

$$
\widehat{K}\left[s_{i}(\alpha)\right](X)=x_{i+1} \partial_{i}(\widehat{K}[\alpha](X))
$$

- For each permutation $w \in \mathbb{S}_{n}$ the double $\beta$-Grothendieck polynomial $\mathcal{G}_{w}^{\beta}(X, Y)$ is defined recursively as follows: if $w=w_{0}$ is the longest element, then $\mathcal{G}_{w_{0}}(X, Y)=R_{\delta}(X, Y)$; if $w$ and $i$ are such that $w_{i}>w_{i+1}$, i.e. $l\left(w s_{i}\right)=l(w)-1$, then

$$
\mathcal{G}_{w s_{i}}^{\beta}(X, Y)=\partial_{i}^{(x)}\left(\left(1+\beta x_{i+1}\right) \mathcal{G}_{w}^{\beta}(X, Y)\right)
$$

- For each permutation $w \in \mathbb{S}_{n}$ the double dual $\beta$-Grothendieck polynomial $\mathcal{H}_{w}^{\beta}(X, Y)$ is defined recursively as follows:
if $w=w_{0}$ is the longest element, then $\mathcal{H}_{w_{0}}(X, Y)=R_{\delta}(X, Y)$;
if $w$ and $i$ are such that $w_{i}>w_{i+1}$, i.e. $l\left(w s_{i}\right)=l(w)-1$, then

$$
\mathcal{H}_{w s_{i}}^{\beta}(X, Y)=\left(1+\beta x_{i}\right) \partial_{i}^{(x)}\left(\mathcal{H}_{w}^{\beta}(X, Y)\right)
$$

- The key $\beta$-Grothendieck polynomials $K G[\alpha](X ; \beta)$ are defined recursively as follows ${ }^{7}$ :
if $\alpha$ is a partition, then $K G[\alpha](X ; \beta)=x^{\alpha}$;
otherwise, if $\alpha$ and $i$ are such that $\alpha_{i}<\alpha_{i+1}$, then

$$
K G\left[s_{i}(\alpha)\right](X ; \beta)=\partial_{i}\left(\left(x_{i}+\beta x_{i} x_{i+1}\right) K G[\alpha](X ; \beta)\right)
$$

- The reduced key $\beta$-Grothendieck polynomials $\widehat{K G}[\alpha](X ; \beta)$ are defined recursively as follows:
if $\alpha$ is a partition, then $\widehat{K G}[\alpha](X ; \beta)=x^{\alpha}$;
otherwise, if $\alpha$ and $i$ are such that $\alpha_{i}<\alpha_{i+1}$, then

$$
\widehat{K G}\left[s_{i}(\alpha)\right](X ; \beta)=\left(x_{i+1}+\beta x_{i} x_{i+1}\right) \partial_{i}(\widehat{K G}[\alpha](X ; \beta)) .
$$

For brevity, we will write $K G[\alpha](X)$ and $\widehat{K G}[\alpha](X)$ instead of $K G[\alpha](X ; \beta)$ and $\widehat{K G}[\alpha](X ; \beta)$.

Remark 4.2 We can also introduce polynomials $\mathcal{Z}_{w}$, which are defined recursively as follows: if $w=w_{0}$ is the longest element, then $\mathcal{Z}_{w_{0}}(X)=x^{\delta}$;
if $w$ and $i$ are such that $w_{i}>w_{i+1}$, i.e. $l\left(w s_{i}\right)=l(w)-1$, then

$$
\mathcal{Z}_{w_{s_{i}}}(X)=\partial_{i}\left(\left(x_{i+1}+x_{i} x_{i+1}\right) \mathcal{Z}_{w}(X)\right)
$$

However, one can show that

$$
\mathcal{Z}_{w}\left(x_{1}, \cdots, x_{n}\right)=\left(x_{1} \cdots x_{n}\right)^{n-1} \mathcal{G}_{w_{0} w w_{0}}\left(x_{n}^{-1}, \cdots, x_{1}^{-1}\right)
$$

Theorem 4.3 The polynomials $\mathfrak{S}_{w}(X, Y), K[\alpha](X), \widehat{K}[\alpha](X), \mathcal{G}_{w}(X, Y), \mathcal{H}_{w}(X, Y)$, $K G[\alpha](X)$ and $\widehat{K G}[\alpha](X)$ have nonnegative integer coefficients.

[^4]We will use notation $\mathfrak{S}_{w}(X), \mathcal{G}_{w}(X), \ldots$, for polynomials $\mathfrak{S}_{w}(X, 0), \mathcal{G}_{w}(X, 0), \ldots$.

## - Di Francesco-Zin-Justin polynomials)

Definition 4.4 For each permutation $w \in \mathbb{S}_{n}$ the Di Francesco-Zinn-Justin polynomials $\mathcal{D} \mathcal{Z}_{w}(X)$ are defined recursively as follows:
if $w$ is the longest element in $\mathbb{S}_{n}$, then $\mathcal{D} \mathcal{Z}_{w}(X)=R_{\delta}(X, 0)$;
otherwise, if $w$ and $i$ are such that $w_{i}>w_{i+1}$, i.e. $l\left(w s_{i}\right)=l(w)-1$, then

$$
\mathcal{D} \mathcal{Z}_{w_{s_{i}}}(X)=\left(\left(1+x_{i}\right) \partial_{i}^{(x)}+\partial_{i}^{(x)}\left(x_{i+1}+x_{i} x_{i+1}\right)\right) \mathcal{D} \mathcal{Z}_{w}(X)
$$

## Conjecture 4.5

(1) Polynomials $\mathcal{D} \mathcal{Z}_{w}(X)$ have nonnegative integer coefficients.
(2) For each permutation $w \in \mathbb{S}_{n}$ the polynomial $\mathcal{D Z}_{w}(X)$ is a linear combination of key polynomials $K[\alpha](X)$ with nonnegative integer coefficients.

As for definition of the double Di Francesco-Zin-Justin polynomials $\mathcal{D} \mathcal{Z}_{w}(X, Y)$ they are well defined, but may have negative coefficients.

- (Hecke-Grothendieck polynomials)

Let $\beta$ and $\alpha$ be two parameters, consider divided difference operator

$$
T_{i}:=T_{i}^{\beta, \alpha}=-\beta+\left((\beta+\alpha)+1+\beta \alpha x_{i} x_{i+1}\right) \partial_{i, i+1} .
$$

## Definition 4.6

Let $w \in \mathbb{S}_{n}$, define Hecke-Grothendieck polynomials $\mathcal{K} \mathcal{N}_{w}^{\beta, \alpha}\left(X_{n}\right)$ to be

$$
\mathcal{K} \mathcal{N}_{w}^{(\beta, \alpha)}\left(X_{n}\right):=T_{w}^{\beta, \alpha}\left(x^{\delta_{n}}\right)
$$

where as before $x^{\delta_{n}}:=x_{1}^{n-1} x_{2}^{n-2} \cdots x_{n-1} ; \quad$ if $u \in \mathbb{S}_{n}$, then set

$$
T_{u}^{\beta, \alpha}:=T_{i_{1}}^{\beta, \alpha} \cdots T_{i_{\ell}}^{\beta, \alpha}
$$

where $u=s_{i_{1}} \cdots s_{i_{\ell}}$ is any reduced decomposition of a permutation taken.

- More generally, let $\beta, \alpha$ and $\gamma$ be parameters, consider divided difference operators
$T_{i}:=T_{i}^{\beta, \alpha, \gamma}=-\beta+\left((\alpha+\beta+\gamma) x_{i}+\gamma x_{i+1}+1+(\beta+\gamma)(\alpha+\gamma) x_{i} x_{i+1}\right) \partial_{i, i+1}, \quad i=1, \ldots, n-1$.
For a permutation $w \in \mathbb{S}_{n}$ define polynomials

$$
\mathcal{K}_{w}^{(\beta, \alpha, \gamma)}\left(X_{n}\right):=T_{i_{1}}^{\beta, \alpha, \gamma} \cdots T_{i_{\ell}}^{\beta, \alpha, \gamma}\left(x^{\delta_{n}}\right)
$$

where $w=s_{i_{1}} \cdots s_{i_{\ell}}$ is any reduced decomposition of $w$.

Remark 4.7 A few comments in order. (a) The divided difference operators $\left\{T_{i}:=\right.$ $\left.T_{i_{1}}^{(\beta, \alpha, \gamma)}, \quad i=1, \cdots, n-1\right\}$ satisfy the following relations

- (Hecke relations)

$$
T_{i}^{2}=(\alpha-\beta) T_{i}+\alpha \beta,
$$

- (Coxeter relations)

$$
T_{i} T_{i+1} T_{i}=T_{i+1} T_{i} T_{i+1}, \quad T_{i} T_{j}=T_{j} T_{i}, \quad \text { if } \quad|i-j| \geq 2
$$

Therefore the elements $T_{w}^{\beta, \alpha}$ are well defined for any $w \in \mathbb{S}_{n}$.

- (Inversion)

$$
\left(1+x T_{i}\right)^{-1}=\frac{1+(\alpha-\beta) x-x T_{i}}{(1-\beta x)(1+\alpha x)}
$$

(b) Polynomials $\mathcal{K} \mathcal{N}_{w}^{(\beta, \alpha, \gamma)}$ constitute a common generalization of the $\beta$-Grothendieck polynomials, namely, $\mathcal{G}_{w}^{(\beta)}=\mathcal{K}^{\mathcal{N}}{ }_{w_{0} w^{-1}}^{(\beta, \alpha=0, \gamma=0)}$,
the Di Francesco-Zin-Justin polynomials, namely, $\mathcal{D} \mathcal{Z}_{w}=\mathcal{K}_{w}^{(\beta=\alpha=1, \gamma=0)}$, the dual $\alpha$-Grothendieck polynomials, namely, $\mathcal{K} \mathcal{N}_{w_{0} w^{-1}}^{(\beta=0, \alpha, \gamma=0)}=\mathcal{H}_{w}^{\alpha}(X)$.

## Proposition 4.8

- (Duality) Let $w \in \mathbb{S}_{n}, \ell=\ell(w)$ denotes its length, then $(\alpha \beta \neq 0)$

$$
\mathcal{K} \mathcal{N}_{w}^{(\beta, \alpha)}(1)=(\beta \alpha)^{\ell} \mathcal{K}_{w^{-1}}^{\left(\alpha^{-1}, \beta^{-1}\right)}(1)
$$

- (Stability) Let $w \in \mathbb{S}_{n}$ be a permutation and $w=s_{i_{1}} s_{i_{2}} \cdots s_{i_{\ell}}$ be any its reduced decomposition. Assume that $i_{a} \leq n-3, \forall 1 \leq a \leq \ell$, and define permutation $\widetilde{w}:=$ $s_{i_{1}+1} s_{i_{2}+1} \cdots s_{i_{\ell}+1} \in \mathbb{S}_{n}$. Then

$$
\mathcal{K N}_{w}^{(\beta, \alpha)}(1)=\mathcal{K} \mathcal{N}_{\widetilde{w}}^{(\beta, \alpha)}(1)
$$

It is well-known that

- the number $\mathcal{K N}_{w_{0}}^{(\beta=1, \alpha=1)}(1)$ is equal to the degree of the variety of pairs commuting matrices of size $n \times n$,
- the bidegree of the affine homogeneous variety $V_{w}, w \in \mathbb{S}_{n}$, [12], is equal to

$$
A^{\binom{n}{2}-\ell(w)} B^{\binom{n}{2}+\ell(w)} \mathcal{K} \mathcal{N}_{w}^{(\beta=\alpha=A / B)}(1) .
$$

see [12], [22], 11] for more details and applications.

## Conjecture 4.9

- Polynomials $\mathcal{K} \mathcal{N}_{w}^{(\beta, \alpha, \gamma)}(X)$ have nonnegative integer coefficients

$$
\mathcal{K}_{w}^{(\beta, \alpha, \gamma)}(X) \in \mathbb{N}[\beta, \alpha, \gamma]\left[X_{n}\right] .
$$

- Polynomials $\mathcal{K} \mathcal{N}_{w}^{(\beta, \alpha, \gamma)}\left(x_{1}=1, \forall i\right)$ have nonnegative integer coefficients

$$
\mathcal{K} \mathcal{N}_{w}^{(\beta, \alpha, \gamma)}\left(x_{i}=1, \forall i\right) \in \mathbb{N}[\beta, \alpha, \gamma] .
$$

- Double polyonomials

$$
\mathcal{K N}_{w}^{(\beta=0, \alpha, \gamma)}(X, Y)=T_{w}^{\beta=0, \alpha, \gamma}(x) \prod_{\substack{i+j \leq n+1 \\ i \geq 1, j \geq 1}}\left(x_{i}+y_{j}\right)
$$

are well defined and have nonnegative integer coefficients.
Note that the assmption $\beta=0$ is necessary.

- Consider permutation $w=[n, 1,2, \cdots, n-1] \in \mathbb{S}_{n}$. Clearly $w=s_{n-1} s_{n-2} \cdots s_{2} s_{1}$.

The number $\mathcal{K}_{w}^{(\beta=1, \alpha=1)}(1)$ is equal to the number of Schröder paths of semilength ( $n$ 1) in which the $(2,0)$-steps come in 3 colors and with no peaks at level 1, see [55], A162326 for further properties of these numbers.
It is well-known, see e.g. [55], A126216, that the polynomial $\mathcal{K N}_{w}^{(\beta, \alpha=0)}(1)$ counts the number of dissections of a convex $(n+1)$-gon according the number of diagonals involved, where as the polynomial $\mathcal{K} \mathcal{N}_{w}^{(\beta, \alpha)}(1)$ (up to a normalization) is equal to the bidegree of certain algebraic varieties introduced and studied by A. Knutson [22].

A few comments in order.
(a) One can consider more general family of polynomials $\mathcal{K} \mathcal{N}_{w}^{(a, b, c, d)}\left(X_{n}\right)$ by the use of the divided difference operators $T_{i}^{a, b, c, d}:=-b+\left((b+d) x_{i}+c x_{i+1}+1+d(b+c) x_{i} x_{i+1}\right) \partial_{i, i+1}^{x}$ istead ot that $T_{i}^{\beta, \alpha, \gamma}$. However the polynomials $\mathcal{K}^{w}{ }^{(a, b, c, d)}(1) \in \mathbb{Z}[a, b, c, d]$ may have negative coefficients in general. Conjecturaly, to ensure the positivity of polynomials $\mathcal{K} \mathcal{N}_{w}^{(a, b, c, d)}\left(X_{n}\right)$, it is necessery take $d:=a+c+r$. In this case we stae Conjecture

$$
\mathcal{K N}_{w}^{(a, b, c, a+c+r)}\left(X_{n}\right) \in \mathbb{N}[a, b, c, r] .
$$

We state more general Conjecture in Introduction. In the present paper we treat only the case $r=0$, since a combinatorial meaning of polynomials $\mathcal{K} \mathcal{N}_{w}^{(a, b, c, a+c+r)}(1)$ in the the case $r \neq 0$ is missed for the author.
(b) If $\gamma \neq 0$, the polynomials $\mathcal{K}^{\mathcal{N}}{ }_{w}^{(\beta, \alpha, \gamma)}\left(X_{n}\right) \in \mathbb{Z}[\alpha, \beta, \gamma]\left[X_{n}\right]$ may have negative negative coefficients in general.

Theorem 4.10 Let $T$ be a semistandard tableau and $\alpha(T)$ be its bottom code, see Definition 2.27 Then

$$
\mathcal{K}_{T}(X)=K[\alpha(T)](X), \quad \mathcal{K} \mathcal{G}_{T}(X)=K G[\alpha(T)](X)
$$

Let $\alpha=\left(\alpha_{1} \leq \alpha_{2} \leq \cdots \leq \alpha_{r}\right)$ be a composition, define partition $\alpha^{+}=\left(\alpha_{r} \geq \cdots \geq \alpha_{1}\right)$.
Proposition 4.11 If $\alpha=\left(\alpha_{1} \leq \alpha_{2} \leq \cdots \leq \alpha_{r}\right)$ is a composition and $n \geq r$, then

$$
K[\alpha]\left(X_{n}\right)=s_{\alpha^{+}}\left(X_{r}\right)
$$

For example, $K[0,1,2, \cdots, n-1]=\prod_{1 \leq i<j \leq n}\left(x_{i}+x_{j}\right)$. Note that $\widehat{K}[0,1,2, \cdots, n-1]=\prod_{i=2}^{n} x_{i}^{i-1}$.

Proposition 4.12 If $\alpha=\left(\alpha_{1} \leq \alpha_{2} \leq \cdots \leq \alpha_{r}\right)$ is a composition and $n \geq r$, then

$$
K G[\alpha]\left(X_{n}\right)=\mathcal{G}\left[\alpha^{+}\right]\left(X_{r}\right) .
$$

For example, $K G[0,1,2, \cdots, n-1]=\prod_{1 \leq i<j \leq n}\left(x_{i}+x_{j}+x_{i} x_{j}\right)$. Note that $\widehat{K G}[0,1,2, \cdots, n-1]=\prod_{i=2}^{n} x_{i}^{i-1} \prod_{i=1}^{n-1}\left(1+x_{i}\right)^{n-i}$.

## Comments 4.1

Definition 4.13 Define degenerate affine $2 d$ nil-Coxeter algebra $\mathcal{A N} \mathcal{C}_{n}^{(2)}$ to be an associative algebra over $\mathbb{Q}$ generated by the set of elements $\left\{\left\{u_{i, j}\right\}_{1 \leq i<j \leq n}\right.$ and $\left.x_{1}, \ldots, x_{n}\right\}$ subject to the set of relations

- $x_{i} x_{j}=x_{j} x_{i} \quad$ for all $i \neq j, \quad x_{i} u_{j, k}=u_{j, k} x_{i}$, if $i \neq j, k$,
- $u_{i . j} u_{k, l}=u_{k, l} u_{i . j}$, if $i, j, k, l$ are pairwise distinct,
- (2d-Coxeter relations) $u_{i, j} u_{j, k} u_{i, j}=U_{j, k} u_{i, j} u_{j, k}, \quad$ if $1 \leq i<j<k \leq n$,
- $x_{i} u_{i . j}=u_{i, j} x_{j}+1, x_{j} u_{i . j}=u_{i, j} x_{i}-1$.

Now for a set of parameters $\sqrt[8]{ } A:=(a, b, c, h, e)$ define elements

$$
T_{i j}:=a+\left(b x_{i}+c x_{j}+h+e x_{i} x_{j}\right) u_{i, j} i<j .
$$

## Lemma 4.14

(1) $T_{i, j}^{2}=(2 a+b-c) T_{i, j}-a(a+b-c)$,
if $a=0$, then $T_{i j}^{2}=(b-c) T_{i j}$.
(2) (2d-Coxeter relations) Relations

$$
T_{i, j} T_{j, k} T_{i, j}=T_{j, k} T_{i, j} T_{j, k},
$$

are valid, if and only if the following relation among parameters a, $, c, e, h$ holds 9

$$
\begin{equation*}
(a+b)(a-c)+h e=0 \tag{4.13}
\end{equation*}
$$

(3) (Yang-Baxter relations) Relations

$$
T_{i, j} T_{i, k} T_{j . k}=T_{j, k} T_{i, k} T_{i, j}
$$

are valid if and only if $b=c=e=0$, i.e. $T_{i j}=a+d u_{i j}$.
(4) $T_{i j}^{2}=1$ if and only if $a= \pm 1, c=b \pm 2, h e=(b \pm 1)^{2}$.

[^5](5) Assume that parameters $a, b, c, h, e$ satisfy the conditions (4.13) and that $b c+1=h e$. Then
$$
T_{i j} x_{i} T_{i j}=(h e-b c) x_{j}+\left(h+(a+b)\left(x_{i}+x_{j}\right)+e x_{i} x_{j}\right) T_{i j} .
$$

Some special cases

- (Representation of affine modified Hecke algebra [58])

If $A=(a,-a, c, h, 0)$, then $T_{i j} x_{i} T_{i j}=a c x_{j}+h T_{i j}, i<j$,

- If $A=(-a, a+b+c, c, 1,(a+c)(b+c)$, then
$T_{i j} x_{i} T_{i j}=a b x_{j}+\left(1+(b+c)\left(x_{i}+x_{j}\right)+(a+c)(b+c) x_{i} x_{j}\right) T_{i j}$.
(6) ( Quantum Yang-Baxter relations, or baxterization of Hecke's algebra generators. ) Assume that parameters $a, b, c, h, e$ satisfy the conditions (4.13) and that $\beta:=2 a+b-c \neq$ 0. Then ( $c f$ [40], [16] and the literature quoted therein)
the elements $R_{i j}(u, v):=1+\frac{\lambda-\mu}{\beta \mu} T_{i j}$ satisfy the twisted quantum Yang-Baxter relations

$$
R_{i j}\left(\lambda_{i}, \mu_{j}\right) R_{j k}\left(\lambda_{i}, \nu_{k}\right) R_{i j}\left(\mu_{j}, \nu_{k}\right)=R_{j k}\left(\mu_{j}, \nu_{k}\right) R_{i j}\left(\lambda_{i}, \nu_{k}\right) R_{j k}\left(\lambda_{i}, \mu_{j}\right), \quad i<j<k
$$

where $\left\{\lambda_{i}, \mu_{i}, \nu_{i}\right\}_{1 \leq i \leq n}$ are parameters. .
Corollary 4.15 If $(a+b)(a-c)+h e=0$, then for any permutation $w \in \mathbb{S}_{n}$ the element

$$
T_{w}:=T_{i_{1}} \cdots T_{i_{l}} \in \mathcal{A N C}{ }_{n}^{(2)},
$$

where $w=s_{i_{1}} \cdots s_{i_{l}}$ is any reduced decomposition of $w$, is well-defined.

## Example 4.16

- Each of the set of elements

$$
\begin{gathered}
s_{i}^{(h)}=1+\left(x_{i+1}-x_{i}+h\right) u_{i, i+1} \quad \text { and } \\
t_{i}^{(h)}=-1+\left(x_{i}-x_{i+1}+h\left(1+x_{i}\right)\left(1+x_{i+1}\right)\right) u_{i j}, \quad i=1, \ldots, n-1,
\end{gathered}
$$

by itself generate the symmetric group $\mathbb{S}_{n}$.

- If one adds the affine elements $s_{0}^{(h)}:=\pi s_{n-1}\left((h) \pi^{-1}\right.$ and $t_{0}^{(h)}:=\pi t_{n-1}^{(h)} \pi^{-1}$, then each of the set of elements $\left\{s_{j}^{(h)}, \quad j \in \mathbb{Z} / n \mathbb{Z}\right\}$ and $\left\{t_{j}^{(h)}, j \in \mathbb{Z} / n \mathbb{Z}\right.$ by itself generate the affine symmetric group $\mathbb{S}_{n}^{a f f}$, see Comments 4.3 for a definition of the transformation $\pi$.
- It seems an interesting problem to classify all rational, trigonometric and elliptic divided difference operators satisfying the Coxeter relations. A general divided difference operator with polynomial coefficients had been constructed in [31], see also Lemma 4.14,(4.13). One can construct a family of rational representations of the symmetric group (as well as its affine extension) by "iterating" the transformations $s_{j}^{(h)}, j \in \mathbb{Z} / n \mathbb{Z}$. For example, take parameters $a$ and $b$, define secondary divided difference operator

$$
\partial_{x y}^{[a, b]}:=-1+(b+y-x) \partial_{x y}^{[a]}, \quad \text { where } \partial_{x y}^{[a]}:=\frac{1-\bar{s}_{x y}^{(a)}}{a-x+y}, \quad \bar{s}_{x y}^{(a)}:=-1+(a+x-y) \partial_{x y} .
$$

Observe that the set of operators $\left\{s_{i}^{[a, b]}:=s_{x_{i}, x_{i+1}}^{[a, b]}, i \in \mathbb{Z} / n \mathbb{Z}\right\}$ gives rise to a rational representation of the affine symmetric group $\mathbb{S}_{n}^{\text {aff }}$ on the field of rational functions $\mathbb{Z}[a, b]\left(X_{n}\right)$. In the special case $a:=A, b:=A / h, h:=1-\beta / 2$ the operators $s_{i}^{[a, b]}$ coincide with operators $\Theta_{i}, i \in \mathbb{Z} / n \mathbb{Z}$ have been introduced in [23], (4.17).

Comments 4.2 Let $A=(a, b, c, h, e)$ be a sequence of integers satisfying the conditions (4.5). Denote by $\partial_{i}^{A}$ the divided difference operator

$$
\partial_{i}^{A}=a+\left(b x_{i}+c x_{i+1}+h+e x_{i} x_{i+1}\right) \partial_{i}, \quad i=1, \ldots, n-1 .
$$

It follows from Lemma 4.10 that the operators $\left\{\partial_{i}^{A}\right\}_{1 \leq i \leq n}$ satisfy the Coxeter relations

$$
\partial_{i}^{A} \partial_{i+1}^{A} \partial_{i}^{A}=\partial_{i+1}^{A} \partial_{i}^{A} \partial_{i+1}^{A}, \quad i=1, \ldots, n-1 .
$$

## Definition 4.17

(1) Let $w \in \mathbb{S}_{n}$ be a permutation. Define the generalized Schubert polynomial corresponding to permutation $w$ as follows

$$
\mathfrak{S}_{w}^{A}\left(X_{n}\right)=\partial_{w^{-1} w_{0}}^{A} x^{\delta_{n}}, \text { where } x^{\delta_{n}}:=x_{1}^{n-1} x_{2}^{n-2} \cdots x_{n-1},
$$

and $w_{0}$ denotes the longest element in the symmetric group $\mathbb{S}_{n}$.
(2) Let $\alpha$ be a composition with at most $n$ parts, denote by $w_{\alpha} \in \mathbb{S}_{n}$ the permutation such that $w_{\alpha}(\alpha)=\bar{\alpha}$, where $\bar{\alpha}$ denotes a unique partition corresponding to composition $\alpha$.

Lemma 4.18 Let $w \in \mathbb{S}_{n}$ be a permutation.

- If $A=(0,0,0,1,0)$, then $\mathfrak{S}_{w}^{A}\left(X_{n}\right)$ is equal to the Schubert polynomial $\mathfrak{S}_{w}\left(X_{n}\right)$.
- If $A=(-\beta, \beta, 0,1,0)$, then $\mathfrak{S}_{w}^{A}\left(X_{n}\right)$ is equal to the $\beta$-Grothendieck polynomial $\mathfrak{G}_{w}^{(\beta)}\left(X_{n}\right)$ introduced in [8].
- If $A=(0,1,0,1,0)$ then $\mathfrak{S}_{w}^{A}\left(X_{n}\right)$ is equal to the dual Grothendieck polynomial.
- If $A=(-1,2,0,1,1)$, then $\mathfrak{S}_{w}^{A}\left(X_{n}\right)$ is equal to the Di-Francesco-Zinn-Justin polynomials introduced in [12].
- If $A=(1,-1,1, h, 0)$, then $\mathfrak{S}_{w}^{A}\left(X_{n}\right)$ is equal to the $h$-Schubert polynomials.

In all cases listed above the polynomials $\mathfrak{S}_{w}^{A}\left(X_{n}\right)$ have non-negative integer coefficients. .
Define the generalized key or Demazure polynomial corresponding to a composition $\alpha$ as follows

$$
K_{\alpha}^{A}\left(X_{n}\right)=\partial_{w_{\alpha}}^{A} x^{\bar{\alpha}}
$$

- If $A=(1,0,1,0,0)$, then $K_{\alpha}^{A}\left(X_{n}\right)$ is equal to key (or Demazure) polynomial corresponding to $\alpha$.
- If $A=(0,0,1,0,0)$, then $K_{\alpha}^{A}\left(X_{n}\right)$ is equal to the reduced key polynomial.
- If $A=(1,0,1,0, \beta)$, then $K_{\alpha}^{A}\left(X_{n}\right)$ is equal to the key Grothendieck polynomial $K G_{\alpha}\left(X_{n}\right)$.
- If $A=(0,0,1,0, \beta)$, then $K_{\alpha}^{A}\left(X_{n}\right)$ is equal to the reduced key Grothendieck polynomials.

In all cases listed above the polynomials $\mathfrak{S}_{w}^{A}\left(X_{n}\right)$ have non-negative integer coefficients. .

- If $A=\left(-1, q^{-1},-1,0,0\right)$ and $\lambda$ is a partition, then (up to a scalar factor) polynomial $K_{\lambda}^{A}\left(X_{n}\right)$ can be identify with a certain Whittaker function (of type A), see [4], Theorem A. Note that operator $T_{i}^{A}:=-1+\left(q^{-1} x_{i}-x_{i+1}\right) \partial_{i}, 1 \leq i \leq n-1$, satisfy the Coxeter and Hecke relations, namely $\left(T_{i}^{A}\right)^{2}=\left(q^{-1}-1\right) T_{i}^{A}+q^{-1}$. In [4] the operator $T_{i}^{A}$ has been denoted by $\mathfrak{T}_{i}$.
- Let $w \in \mathbb{S}_{n}$ be a permutation and $\mathfrak{m}=\left(i_{1}, \ldots, i_{\ell}\right)$ be a reduced word for $w$, i.e. $w=$ $s_{i_{1}} \cdots s_{i_{\ell}}$ and $\ell(w)=\ell$. Denote by $Z_{\mathfrak{m}}$ the Bott-Samelson nonsingular variety corresponding to the reduce word $\mathfrak{m}$. It is well-known that the Bott-Samelson variety $Z_{\mathfrak{m}}$ is birationally isomorphic to the Schubert variety $X_{w}$ associated with permutation $w$, i.e. the Bott-Samelson variety $Z_{\mathfrak{m}}$ is a desingularization of the Schubert variety $X_{w}$. Follow [4] define the BottSamelson polynomials $Z_{\mathfrak{m}}(x, \lambda, v)$ as follows

$$
Z_{\mathfrak{m}}(x, \lambda, v)=\left(1+T_{i_{1}}^{A}\right) \cdots\left(1+T_{i_{\ell}}^{A}\right) x^{\lambda}
$$

where $A=(-v,-1,1,0)$. Note that $\left(1+T_{i}^{A}\right)^{2}=(1+v)\left(1+T_{i}^{A}\right)$, and the divided difference operators $1+T_{i}^{A}=1+v+\left(x_{i+1}-v x_{i}\right) \partial_{i}$ do not satisfy the Coxeter relations.

- If $A=(-\beta, \beta+\alpha, 0,1, \beta \alpha)$, then $\mathfrak{S}_{w}^{A}\left(X_{n}\right)$ constitutes a common generalization of the Grothendieck and the Di Francesco-Zin-Justin polynomials.
- If $A=(t,-1, t, 1,0)$, then the divided difference operators

$$
T_{i}^{A}:=t+\left(-x_{i}+t x_{i+1}+1\right) \partial_{i}, \quad 1 \leq i \leq n-1
$$

their baxterizations) and the raising operator

$$
\phi:=\left(x_{n}-1\right) \pi,
$$

where $\pi$ denotes the $q^{-1}$-shift operator, namely $\pi\left(x_{1}, \ldots, x_{n}\right)=\left(x_{n} / q, x_{1}, \ldots, x_{n-1}\right)$, can be used to generate the interpolation Macdonald polynomials as well as the nonsymmetric Macdonald polynomials, see [41] for details.

In similar fashion, rely on the operators and its baxterization
$T_{i}^{\beta, \alpha, \gamma, h}:=-\beta+\left((\alpha+\beta+\gamma) x_{i}+\gamma x_{i+1}+h+h^{-1}(\alpha+\gamma)(\beta+\gamma) x_{i} x_{i+1}\right) \partial_{i}, \quad 1 \leq i \leq n-1$, and $\phi$, we introduce polynomials $M_{\delta}^{\beta, \alpha, \gamma, q}\left(X_{n}\right)$, where $\delta$ is a composition. These polynomials are common generalization of the interpolation Macdonald polynomials $M_{\delta}\left(X_{n} ; q, t\right)$ (the case $\overline{\beta=-t, \alpha=-1, \gamma=t}$ ), as well as the Schubert, $\beta$-Grothendieck and its dual, Demazure and Di Francesco-Zin-Justin polynomials, and conjecturally their affine analogues/versions. Details will appear elsewhere.

Comments 4.3 (Double affine NilCoxeter algebra) Let $t, q, a, b, c, h, d$ be parameters.

Definition 4.19 Define double affine nil-Coxeter algebra $D A N C_{n}$ to be (unital) associative algebra over $\mathbb{Q}\left(q^{ \pm 1}, t^{ \pm 1}\right)$ with the set of generators $\left\{e_{1}, \ldots, e_{n-1}, x_{1}, \ldots, x_{n}, \pi^{ \pm 1}\right\}$ subject to relations

- (NilCoxeter relations)
$e_{i} e_{j}=e_{j} e_{i}, \quad$ if $|i-j| \geq 2, \quad e_{i}^{2}=0, \forall i, \quad e_{i} e_{j} e_{i}=e_{j} e_{i} e_{j}, \quad$ if $\quad|i-j|=1 ;$
- (Crossing relations)

$$
x_{i} e_{k}=e_{k} x_{i}, \quad \text { if } \quad k \neq i, i+1, \quad x_{i} e_{i}-e_{i} x_{i+1}=1, \quad e_{i} x_{i}-x_{i+1} e_{i}=1 ;
$$

- (Affine crossing relations)

$$
\begin{aligned}
& \pi x_{i}=x_{i+1} \pi, \quad \text { if } i<n, \quad \pi x_{n}=q^{-1} x_{1} \pi \\
& \pi e_{i}=e_{i+1} \pi, \quad \text { if } \quad i<n-1, \quad \pi^{2} e_{n-1}=q e_{1} \pi^{2} .
\end{aligned}
$$

Now let us introduce elements $\quad e_{0}:=\pi e_{n-1} \pi^{-1}$ and

$$
T_{0}:=T_{0}^{a, b, c, h, d}=\pi T_{n-1} \pi^{-1}=a+\left(b x_{n}+q^{-1} c x_{1}+h+q^{-1} d x_{1} x_{n}\right) e_{0} .
$$

It is easy to see that $\pi e_{0}=q e_{1} \pi$,

$$
\pi T_{0}^{a, b, c, h, d}=T_{1}^{a, b, c, q} h_{, q^{-1} d} e_{1} \pi=T_{1}^{a, b, c, h, d}+\left((1-q) h+\left(1-q^{-1}\right) d x_{1} x_{2}\right) e_{1} .
$$

Now let us assume that $a=t, b=-t, d=e=0, c=1$. Then, $T_{i}=t+\left(x_{i+1}-t x_{i}\right) e_{i}, i=1, \ldots, n-1, T_{0}=t+\left(q^{-1} x_{1}-t x_{n}\right) e_{0}$,

$$
T_{i}^{2}=(t-1) T+t, \quad 0 \leq i<n, \quad T_{i} x_{i} T_{i}=t x_{i+1}, \quad 1 \leq i<n, T_{0} x_{n} T_{0}=t q^{-1} x_{1},
$$

$$
T_{0} T_{1} T_{0}=T_{1} T_{0} T_{1}, T_{n-1} T_{0} T_{n-1}=T_{0} T_{n-1} T_{0}, T_{0} T_{i}=T_{i} T_{0}, \quad \text { if } 2 \leq i<n-1
$$

The operators $T_{i}:=T_{i}^{t,-t, 1,0,0}, \quad 0 \leq i \leq n-1$ have been used in 41 to give an "elementary" construction of nonsymmetric Macdonald polynomials. Indeed, one can realize the operator $\pi$ as follows:

$$
\pi(f)=f\left(x_{n} / q, x_{1}, x_{2}, \ldots, x_{n-1}\right), \text { so that } \pi^{-1}(f)=\left(x_{2}, \ldots, x_{n}, q x_{1}\right)
$$

and introduce the raising operator [41] to be

$$
\phi\left(f\left(X_{n}\right)\right)=\left(x_{n}-1\right) \pi\left(f\left(X_{n}\right)\right) .
$$

It is easily seen that $\phi T_{i}=T_{i+1} \phi, \quad i=0, \cdots, n-2, \quad$ and $\quad \phi^{2} T_{n-1}=T_{1} \phi^{2}$. It has been established in [41] how to use the operators $\phi, T_{1}, \ldots, T_{n-1}$ to to give formulas for the interpolation Macdonald polynomials. Using operators $\phi, T_{i}^{(a, b, c, h, d)}, i=1, \ldots, n-1$ instead of $\phi, T_{1}, \ldots, T_{n-1}, 1 \leq i \leq n-1$, one get a 4 -parameter generalization of the interpolation Macdonald polynomials, as well as the nonsymmetric Macdonald polynomials.

It follows from the nilCoxeter relations listed above, that the Dunkl-Cherednik elements, cf [5]

$$
Y_{i}:=\left(\prod_{a=i-1}^{1} T_{a}^{-1}\right) \pi\left(\prod_{a=n-1}^{i+1} T_{a}\right), \quad i=1, \ldots, n
$$

where $T_{i}=T_{i}^{t,-t, 1,0,0}$, generate a commutative subalgebra in the double affine nilCoxeter algebra $D A N C_{n}$. Note that the algebra $D A N C_{n}$ contains lot of other interesting commutative subalgebras, see e.g. [16].

It seems interesting to give an interpretation of polynomials generated by the set of operators $T_{i}^{t,-t, 1, h, e}, i=0, \cdots, n-1$ in a way similar to that given in [41]. We expect that these polynomials provide an affine version of polynomials $\mathcal{K} \mathcal{N}_{w}^{(-t,-1,1,1,0)}(X), w \in \mathbb{S}_{n} \subset \mathbb{S}_{n}^{a f f}$, see Remark 4.7.

Note that for any affine permutation $v \in \mathbb{S}_{n}^{a f f}$, the operator

$$
T_{v}^{(a, b, c, h, d)}=T_{i_{1}}^{(a, b, c, h, d)} \cdots T_{i_{\ell}}^{(a, b, c, h, d)}
$$

where $v=s_{i_{1}} \cdots s_{i_{\ell}} \quad$ is any reduced decomposition of $v$, is well-defined up to the sign $\pm 1$. It seems an interesting problem to investigate properties of polynomials $L_{v}[\alpha]\left(X_{n}\right)$, where $v \in \mathbb{S}_{n}^{\text {aff }}$ and $\alpha \in \mathbb{Z}_{\geq 0}^{n}$, and find its algebra-geometric interpretations.

## 5 Cauchy kernel

Let $u_{1}, u_{2}, \cdots, u_{n-1}$ be a set of generators of the free algebra $\mathcal{F}_{n-1}$, which assumed also to be commute with the all variables $\mathfrak{P}_{n}:=\left\{p_{i, j}, 2 \leq i+j \leq n+1, i \geq 1, j \geq 1\right\}$..

Definition 5.1 The Cauchy kernel $\mathcal{C}\left(\mathfrak{P}_{n}, U\right)$ is defined to be as the ordered product

$$
\begin{equation*}
\mathcal{C}\left(\mathfrak{P}_{n}, U\right)=\prod_{i=1}^{n-1}\left\{\prod_{j=n-1}^{i}\left(1+p_{i, j-i+1} u_{j}\right)\right\} . \tag{5.14}
\end{equation*}
$$

For example,

$$
\mathcal{C}\left(\mathfrak{P}_{4}, U\right)=\left(1+p_{1,3} u_{3}\right)\left(1+p_{1,2} u_{2}\right)\left(1+p_{1,1} u_{1}\right)\left(1+p_{2,2} u_{3}\right)\left(1+p_{2,1} u_{2}\right)\left(1+p_{3,1} u_{3}\right)
$$

In the case $\left\{p_{i j}=x_{i}, \forall j\right\}$ we will write $\mathcal{C}_{n}(X, U)$ instead of $\mathcal{C}\left(\mathfrak{P}_{n}, U\right)$.

## Lemma 5.2

$$
\begin{equation*}
\mathcal{C}\left(\mathfrak{P}_{n}, U\right)=\sum_{(\mathbf{a}, \mathbf{b}) \in \mathcal{S}_{n}} \prod_{j=1}^{p} p_{\left\{a_{j}, b_{j}\right\}} w(\mathbf{a}, \mathbf{b}) \tag{5.15}
\end{equation*}
$$

where $\mathbf{a}=\left(a_{1}, \ldots, a_{p}\right), \quad \mathbf{b}=\left(b_{1}, \ldots, b_{p}\right), w(\mathbf{a}, \mathbf{b})=\prod_{j=1}^{p} u_{a_{j}+b_{j}-1}$, and the sum in (4.10) runs over the set $\mathcal{S}_{n}:=$
$\left\{(\mathbf{a}, \mathbf{b}) \in \mathbb{N}^{p} \times \mathbb{N}^{p} \mid \mathbf{a}=\left(a_{1} \leq a_{2} \leq \ldots \leq a_{p}\right), a_{i}+b_{i} \leq n, \quad\right.$ and if $\left.a_{i}=a_{i+1} \Longrightarrow b_{i}>b_{i+1}\right\}$.

We denote by $\mathcal{S}_{n}^{(0)}$ the set $\left\{(\mathbf{a}, \mathbf{b}) \in \mathcal{S}_{n} \mid w(\mathbf{a}, \mathbf{b})\right.$ is a tableau word $\}$.
The number of terms in the right hand side of (5.15) is equal to $2^{\binom{n}{2}}$, and therefore is equal to the number $\#\left|S T Y\left(\delta_{n}, \leq n\right)\right|$ of semistandard Young tableaux of the staircase shape $\delta_{n}:=$ $(n-1, n-2, \ldots, 2,1)$ filled by the numbers from the set $\{1,2, \ldots, n\}$. It is also easily seen that the all terms appearing in the $R H S(4.10)$ are different, and thus $\#\left|\mathcal{S}_{n}\right|=\#\left|S T Y\left(\delta_{n}, \leq n\right)\right|$.

We are interested in the decompositions of the Cauchy kernel $\mathcal{C}\left(\mathfrak{P}_{n}, U\right)$ in the algebras $\mathcal{P}_{n}, \quad \mathcal{N} \mathcal{P}_{n}, \mathcal{I} \mathcal{P}_{n}, \mathcal{N C}{ }_{n}$ and $\mathcal{I C}_{n}$.

### 5.1 Plactic algebra $\mathcal{P}_{n}$

Let $\lambda$ be a partition and $\alpha$ be a composition of the same size. Denote by $\widetilde{\operatorname{STY}}(\lambda, \alpha)$ the set of semistandard Young tableaux $T$ of the shape $\lambda$ and content $\alpha$ which must satisfy the following conditions:

- for each $k=1,2, \cdots$, the all numbers $k$ are located in the first $k$ columns of the tableau $T$. In other words, the all entries $T(i, j)$ of a semistandard tableau $T \in \widetilde{S T Y}(\lambda, \alpha)$ have to satisfy the following conditions: $\quad T_{i, j} \leq j$.

For a given (semi-standard) Young tableau $T$ let us denote by $R_{i}(T)$ the set of numbers placed in the $i$-th row of $T$, and denote by $\widetilde{S T Y}_{0}(\lambda, \alpha)$ the subset of the set $\widetilde{S T Y}_{0}(\lambda, \alpha)$ involving only tableaux $T$ which satisfy the following constrains : $R_{1}(T) \supset R_{2}(T) \supset R_{3}(T) \supset$

To continue, let us denote by $\mathcal{A}_{n}$ (respectively by $\mathcal{A}_{n}^{(0)}$ ) the union of the sets $\widetilde{\operatorname{STY}}(\lambda, \alpha)$ (resp. that of $\left.\widetilde{S T Y}_{0}(\lambda, \alpha)\right)$ for all partitions $\lambda$ such that $\lambda_{i} \leq n-i$ for $i=1,2, \cdots, n-1$, and all compositions $\alpha, l(\alpha) \leq n-1$. Finally, denote by $\mathcal{A}_{n}(\lambda)$ (resp. $\left.\mathcal{A}_{n}^{(0)}(\lambda)\right)$ the subset of $\mathcal{A}_{n}\left(\right.$ resp. $\left.\mathcal{A}_{n}^{(0)}(\lambda)\right)$ consisting of all tableaux of the shape $\lambda$.

## Lemma 5.3

- $\left|\mathcal{A}_{n}\left(\delta_{n}\right)\right|=1,\left|\mathcal{A}_{n}\left(\delta_{n-1}\right)\right|=(n-1)!,\left|\mathcal{A}_{n}((n-1))\right|=C_{n-1}$ the $n-1$-th Catalan number. More generally,

$$
\left|\mathcal{A}_{n}\left(\left(1^{k}\right)\right)\right|=\binom{n-1}{k}, \quad\left|\mathcal{A}_{n}((k))\right|=\frac{n-k}{n}\binom{n+k-1}{k}, \quad k=0, \ldots, n-1
$$

cf [55], A009766,

$$
\left\lvert\, \mathcal{A}_{n}((k, 1))=\frac{(n-k+1)\left(n^{2}+n-k-1\right)}{(k+1)(n+2)}\binom{n+k}{k-1}\right., k=1, \ldots, n
$$

- There exists a bijection $\rho_{n}: \mathcal{A}_{n} \longrightarrow A S M(n)$ such that the image Im $\left(\mathcal{A}_{n}^{(0)}\right)$ contains the set of $n \times n$ permutation matrices.
- The number of column strict, as well as row strict diagrams which are contained inside the staircase diagram $(n, n-1, \ldots, 2,1)$ is equal to $2^{n}$.

Example 5.4 Take $n=5$ so that $A S M(5)=429$ and $\operatorname{Cat}(5)=42$. One has

$$
\begin{aligned}
& \quad\left|\mathcal{A}_{5}^{(0)}\right|=\left|\mathcal{A}_{5}^{(0)}(\emptyset)\right|+\left|\mathcal{A}_{5}^{(0)}((1))\right|+\left|\mathcal{A}_{5}^{(0)}((2))\right|+\left|\mathcal{A}_{5}^{(0)}((3))\right|+\left|\mathcal{A}_{5}^{(0)}((2,1))\right|+\left|\mathcal{A}_{5}^{(0)}((4))\right|+ \\
& \left|\mathcal{A}_{5}^{(0)}((3,1))\right|+\left|\mathcal{A}_{5}^{(0)}((3,2))\right|+\left|\mathcal{A}_{5}^{(0)}((4,1))\right|+\left|\mathcal{A}_{5}^{(0)}((4,2))\right|+\left|\mathcal{A}_{5}^{(0)}((3,2,1))\right|+\left|\mathcal{A}_{5}^{(0)}((4,3))\right|+ \\
& \left|\mathcal{A}_{5}^{(0)}((4,2,1))\right|+\left|\mathcal{A}_{5}^{(0)}((4,3,1))\right|+\left|\mathcal{A}_{5}^{(0)}((4,3,2))\right|+\left|\mathcal{A}_{5}^{(0)}((4,3,2,1))\right|= \\
& 1+4+9+14+6+14+16+4+21+14+4+1+9+2+1+1=121, \\
& \quad \sum_{k=0}^{4}\left|\mathcal{A}_{5}((k))\right|=1+4+9+14+14=42 .
\end{aligned}
$$

We expect that the image $\rho_{n}\left(\bigcup_{k=0}^{n-1} \mathcal{A}_{n}((k))\right)$ coincides with the set of $n \times n$ permutation matrices corresponding to either 321-avoiding or 132 -avoiding permutations.

Now we are going to define a statistic $n(T)$ on the set $\mathcal{A}_{n}$.
Definition 5.5 Let $\lambda$ be a partition, $\alpha$ be a composition of the same size. For each tableau $T \in \widetilde{S T Y}(\lambda, \alpha) \subset \mathcal{A}_{n}(\lambda)$ define

$$
n(T)=\alpha_{n}=\operatorname{Card}\{(i, j) \in \lambda \mid T(i, j)=n\}
$$

Clearly, $n(T) \leq \lambda_{1}$.
Define polynomials

$$
\mathcal{A}_{\lambda}(t):=\sum_{T \in \mathcal{A}_{n}(\lambda)} t^{\lambda_{1}-n(T)} .
$$

It is instructive to display the numbers $\left\{\mathcal{A}_{n}(\lambda), \lambda \subset \delta_{n}\right\}$ as a vector of the length equals to the $n-t h$ Catalan number. For example,
$\mathcal{A}_{4}(\emptyset,(1),(2),(1,1),(3),(2,1),(1,1,1),(3,1),(2,2),(2,1,1),(3,2),(3,1,1),(2,2,1),(3,2,1))=$ $(1,3,5,3,5,6,1,6,3,2,3,2,1,1)$.

It is easy to see that the above data, as well as the corresponding data for $n=5$, coincide with the list of refined totally symmetric self-complementary plane partitions that fit in the box $2 n \times 2 n \times 2 n(\operatorname{TSSCPP}(n)$ for short) listed for $n=1,2,3,4,5$ in [12], Appendix D.

In fact we have
Theorem 5.6 The sequence $\left\{\mathcal{A}_{n}(\lambda), \lambda \subset \delta_{n}\right\}$ coincides with the set of refined TSSCPP $(n)$ numbers as defined in [12]. More precisely,

- $\left|\mathcal{A}_{n}(\lambda)\right|=\operatorname{det}\left|\binom{n-i}{\lambda_{j}^{\prime}-j+i}\right|_{1 \leq i, j \leq n-1}$,
- We have

$$
\mathcal{A}_{\lambda}(t):=\operatorname{det}\left|\binom{n-i-1}{\lambda_{j}^{\prime}-j+i-1}+t\binom{n-i-1}{\lambda_{j}^{\prime}-j+i}\right|_{1 \leq i, j \leq n-1},
$$

- Polynomial $\mathcal{A}_{\lambda}(t)$ is equal to a t-analog of refined $\operatorname{TSSCPP}(n)$ numbers $P_{n}\left(\lambda_{n-1}^{\prime}+\right.$ $\left.1, \cdots, \lambda_{n-i}^{\prime}+i, \cdots, \lambda_{1}^{\prime}+n-1 \mid t\right)$ introduced by means of recurrence relations in [12], (3.5).

In particular, $\sum_{\lambda \subset \delta_{n}} \mathcal{A}_{\lambda}(t)=\sum_{1 \leq j \leq n-1} A_{n, j} t^{j-1}$, where $A_{n, j}$ stands for the number of alternating sign matrices $\left(A S M_{n}\right.$ for short) of size $n \times n$ with a 1 on top of the j -th column.

Corollary 5.7 The number of different tableau subwords in the word

$$
w_{0}:=\prod_{j=1}^{n-1}\left\{\prod_{a=n-1}^{j} a\right\}
$$

is equal to the number of alternating sign matrices of size $n \times n$, i.e.

$$
\left|\mathcal{A}_{n}\right|=|T S S C P P(n)|=\left|A S M_{n}\right| .
$$

It is well-known [3] that

$$
A_{n, j}=\binom{n+j-2}{j-1} \frac{(2 n-j-1)!}{(n-j)!} \prod_{i=0}^{n-2} \frac{(3 i+1)!}{(n+i)!}
$$

and the total number $A_{n}$ of $A S M$ of size $n \times n$ is equal to

$$
A_{n} \equiv A_{n+1,1}=\sum_{j=1}^{n} A_{n, j}=\prod_{i=0}^{n-1} \frac{(3 i+1)!}{(n+i)!}
$$

## Comments 5.1

(1) Let as before $\operatorname{STY}\left(\delta_{n} \leq n\right):=\mathcal{S} \mathcal{T}_{n}$ denotes the set of all semistandard Young tableaux of the staircase shape $\delta_{n}=(n-1, n-2, \ldots, 2,1)$ filled by the numbers from the set $\{1, \ldots, n\}$. Denote by $\mathcal{S} \mathcal{T}_{n}^{(0)}$ the subset of "anti- diagonally" increasing tableaux, i.e.

$$
\mathcal{S} \mathcal{T}_{n}^{(0)}=\left\{T \in S T Y\left(\delta_{n}, \leq n\right) \mid T_{i, j} \geq T_{i-1, j+1} \quad \text { for all } 2 \leq i \leq n-1, \quad 1 \leq j \leq n-2\right\}
$$

One (A.K) can construct bijections

$$
\iota_{n}: \mathcal{S}_{n} \sim \mathcal{S} \mathcal{T}_{n}, \quad \zeta_{n}: \mathcal{A}_{n} \sim \mathcal{S} \mathcal{T}_{n}^{(0)}
$$

such that $\operatorname{Im}\left(\iota_{n}\right)=\operatorname{Im}\left(\zeta_{n}\right)$.

## Proposition 5.8

$$
\left.\begin{array}{c}
\sum_{\substack{\lambda=\left(\lambda_{1}, \ldots, \lambda_{n}\right) \\
\rho_{n} \geq \lambda}} K_{\rho_{n}, \lambda}\left(\begin{array}{c}
n \\
m_{0}(\lambda), \\
m_{1}(\lambda),
\end{array} \ldots, \quad m_{n}(\lambda)\right)=2^{\binom{n}{2} .} \\
\sum_{\substack{\lambda=\left(\lambda_{1}, \ldots, \lambda_{n}\right) \\
\rho_{n} \geq \lambda}}\left(\begin{array}{ccc}
n \\
m_{0}(\lambda), & m_{1}(\lambda), & \ldots,
\end{array} m_{n}(\lambda)\right.
\end{array}\right)=\mathcal{F}_{n}, .
$$

where $\mathcal{F}_{n}$ denotes the number of forests of trees on $n$ labeled nodes;
$K_{\rho_{n}, \lambda}$ denotes the Kostka number, i.e. the number of semistandard Young tableaux of the shape $\rho_{n}:=(n-1, n-2, \ldots, 1)$ and content/weight $\lambda$;
for any partition $\lambda=\left(\lambda_{1} \geq \lambda_{2} \geq \ldots \geq \lambda_{n} \geq 0\right)$ we set $m_{i}(\lambda)=\left\{j \mid \lambda_{j}=i\right\}$.

Let $\alpha$ be a composition, we denote by $\alpha^{+}$the partition obtained from $\alpha$ by reordering of its parts. For example, if $\alpha=(0,2,0,3,1,0)$ then $\alpha^{+}=(3,2,1)$. Note that $\ell(\alpha)=6$, but $\ell\left(\alpha^{+}\right)=3$.

Now let $\alpha$ be a composition such that $\rho_{n} \geq \alpha^{+}, \quad \ell(\alpha) \leq n$, that is $\alpha_{j}=0$, if $j>\ell(\alpha)$, $|\alpha|=\binom{n}{2}$ and

$$
\sum_{k \leq j}\left(\rho_{n}\right)_{k} \geq \sum_{k \leq j}\left(\alpha^{+}\right)_{k}, \forall j .
$$

There is a unique semistandard Young tableau $T_{n}(\alpha)$ of shape $\rho_{n}$ and content $\alpha$ which corresponds to the maximal configuration of type ( $\rho_{n} ; \alpha$ ) and has all quantum numbers (riggings) equal to zero. It follows from Proposition 4.8 that $\#\left\{\alpha \mid \ell(\alpha) \leq n, \rho_{n} \geq \alpha^{+}\right\}=\mathcal{F}_{n}$. Therefore there is a natural embedding of the set of forests on $n$ labeled nodes to the set of semistandard Young tableaux of shape $\rho_{n}$ filled by the numbers from the set $[1, \ldots, n]$. We denote by $\mathcal{F} \mathcal{T}_{n} \subset S T Y\left(\rho_{n}, \leq n\right)$ the subset $\left\{T_{n}(\alpha) \mid \rho_{n} \geq \alpha^{+}, \ell(\alpha) \leq n\right\}$. Note that the set $\mathcal{K}_{n}:=\left\{\alpha \mid \ell(\alpha)=n,(\alpha)^{+}=\rho_{n}\right\}$ contains $n!$ compositions, and under the rigged configuration bijection the elements of the set $\mathcal{K}_{n}$ correspond to the key tableaux of shape $\rho_{n}$.

Let us say a few words about the Kostka numbers $K_{\rho_{n}, \alpha}$. First of all, it's clear that if $\alpha=\left(\alpha_{1}, \alpha_{2}, \cdots\right)$ is a composition such that $\alpha_{1}=n-1$, then $K_{\rho_{n}, \alpha}=K_{\rho_{n-1}, \alpha[1]}$, where we set $\alpha[1]:=\left(\alpha_{2}, \ldots\right)$.

Now assume that $n=2 k+1$ is an odd integer, and consider partitions $\nu_{n}:=\left(k^{n}\right)$ and $\mu_{n}:=\left((k+1)^{k}, k^{k}\right)$. Then

$$
K_{\rho_{n}, \nu_{n}}=\operatorname{Coeff} f_{\left(x_{1} x_{2} \cdots x_{n}\right)^{k}}\left(\prod_{1 \leq i<j \leq n}\left(x_{i}+x_{j}\right)\right), \quad\binom{2 k}{k} K_{\rho_{n}, \mu_{n}}=K_{\rho_{n}, \nu_{n}} .
$$

It is well-known that the number $K_{\rho_{n}, \nu_{n}}$ is equal to number of labeled regular tournaments with $n:=2 k+1$ nodes, see e.g. [55], $A 007079$.

In the case when $n=2 k$ is an even number, one can show that

$$
K_{\rho_{n}, \nu_{n}}=K_{\rho_{n-1}, \nu_{n-1}}, \quad K_{\rho_{n}, \mu_{n}}=K_{\rho_{n+1}, \mu_{n+1}} .
$$

Note that the rigged configuration bijection gives rise to an embedding of the set of labeled regular tournaments with $n:=2 k+1$ nodes to the set $S T Y\left(\rho_{n}, \leq n\right)$, if $n$ is an odd integer, and to the set $\operatorname{STY}\left(\rho_{n-1}, \leq n-1\right)$, if $n$ is even.

## Theorem 5.9

(1) In the plactic algebra $\mathcal{P}_{n}$ the Cauchy kernel has the following decomposition

$$
\begin{equation*}
\mathcal{C}_{n}(\mathfrak{P}, U)=\sum_{T \in \mathcal{A}_{n}} \mathcal{K}_{T}(\mathfrak{P}) u_{w(T)} . \tag{5.16}
\end{equation*}
$$

(2) Let $T \in \mathcal{A}_{n}$, and $\alpha(T)$ be its bottom code. Then

$$
\mathcal{K}_{T}(\mathfrak{P})-\prod_{(i, j) \in T} p_{\{i, T(i, j)-j+1\}} \geq 0
$$

and equality holds if and only if the bottom code $\alpha(T)$ is a partition.
Note that the number of different shapes among the tableaux in the set $\mathcal{A}_{n}$ is equal to the Catalan number $C_{n}:=\frac{1}{n+1}\binom{2 n}{n}$.

Problem 5.10 Construct a bijection between the set $\mathcal{A}_{n}$ and the set of alternating sign matrices $A S M_{n}$.

Example 5.11 For $n=4$ one has $\mathcal{C}_{4}(X, U)=K[0]+$
$K[1] u_{1}+$
$K[01] u_{2}+$
$K[001] u_{3}+$
$K[11]\left(u_{12}+u_{22}\right)+$
$K[2]\left(u_{21}+u_{31}\right)+$
$K[101] u_{13}+$
$K[02] u_{32}+$
$K[011]\left(u_{23}+u_{33}\right)+$
$K[3] u_{321}+$
$K[12]\left(u_{312}+u_{322}\right)+$
$K[21] u_{212}+$
$K[111]\left(u_{123}+u_{133}+u_{233}+u_{223}+u_{333}\right)+$
$K[021] u_{323}+$
$K[201]\left(u_{313}+u_{213}\right)+$
$K[31] u_{3212}+$
$K[301] u_{3213}+$
$K[22]\left(u_{3132}+u_{2132}+u_{3232}\right)+$
$K[121]\left(u_{3123}+u_{3233}+u_{3223}\right)+$
$K[211]\left(u_{2123}+u_{2133}+u_{3133}\right)+$
$K[32] u_{32132}+$
$K[311]\left(u_{32123}+u_{32133}\right)+$
$K[221]\left(u_{21323}+u_{31323}+u_{32323}\right)+$
$K[321] u_{321323}$.
Let $w \in \mathbb{S}_{n}$ be a permutation with the Lehmer code $\alpha(w)$.
Definition 5.12 Define the plactic polynomial $\mathcal{P} \mathcal{L}_{w}(E)$ to be

$$
\mathcal{P} \mathcal{L}_{w}(U)=\left\{\sum_{T \in \mathcal{A}_{n}, \alpha(T)=\alpha(w)} u_{w(T)}\right\} .
$$

Comments 5.2 It is easily seen from a definition of the Cauchy kernel that

$$
\mathcal{C}_{n}(X, U)=\sum_{\alpha \subset \delta_{n}} K[\alpha](X) \mathcal{P} \mathcal{L}_{w_{0} w_{\alpha}^{-1}}(U),
$$

where $w_{\alpha}$ denotes a unique permutation in $\mathbb{S}_{n}$ with code equals $\alpha ; K[\alpha](X)$ denotes the key polynomial corresponding to composition $\alpha \subset \delta_{n}$. The polynomials $\mathcal{P} \mathcal{L}_{w_{0} w_{\alpha}^{-1}}$ can be treated as a plactic version of noncommutative Schur and Schubert polynomials introduced and studied in 21, [32, [7], 42, 38].

Now let $X=\left\{x_{1}, \ldots, x_{n}\right\}$ be a set of mutely commuting variables, and
$I_{0}:=\{\underbrace{n-1, n-2, \ldots, 2,1}_{n-1}, \ldots, \underbrace{n-1,, n-2, \ldots, k+1, k}_{n-k}, \ldots, n-1, n-2, n-1\}$ be lexicographically maximal reduced expression for the longest element $w_{0} \in \mathbb{S}_{n}$. Let $I$ be a tableau subword ${ }^{10}$ of the set $I_{0}$. One can show $(A K)$ that under the specialization

$$
u_{i}= \begin{cases}x_{i}, & \text { if } i \in I_{0} \backslash I, \\ 1, & \text { if } i \in I\end{cases}
$$

the polynomial $\mathcal{P} \mathcal{L}_{w_{0} w_{\alpha}^{-1}}(U)$ turns into the Schubert polynomial $\mathfrak{S}_{w_{\alpha}}(X)$. In a similar fashion, consider the decomposition

$$
\mathcal{C}_{n}(X, U)=\sum_{\alpha \subset \delta_{n}} K G[\alpha](X ;-\beta) \mathcal{P} \mathcal{L}_{w_{0} w_{\alpha}^{-1}}(U ; \beta) .
$$

One can show $(A K)$ that under the same specialization as has been listed above, the polynomial $\mathcal{P}_{w_{0} w_{\alpha}^{-1}}(U ; \beta)$ turns into the $\beta$-Grothendieck polynomial $\mathcal{G}_{w_{\alpha}}^{\beta}(X)$.

Definition 5.13 Define algebra $\mathcal{P C}_{n}$ to be the quotient of the plactic algebra $\mathcal{P}_{n}$ by the twosided ideal $J_{n}$ by the set of monomials

$$
\left\{u_{i_{1}} u_{i_{2}} \cdots u_{i_{n}}\right\}, \quad 1 \leq i_{1} \leq i_{2} \leq \cdots \leq i_{n} \leq n, \quad \#\left\{a \mid i_{a}=j\right\} \leq j, \forall j=1, \ldots, n
$$

## Theorem 5.14

- The algebra $\mathcal{P C}_{n}$ has dimension equals to $\operatorname{ASM}(n)$,
- $\operatorname{Hilb}\left(\mathcal{P C}_{n}, q\right)=\sum_{\lambda \in \delta_{n-1}}\left|\mathcal{A}_{\lambda}\right| q^{|\lambda|}$,
- $\operatorname{Hill}\left(\left(\mathcal{P C}_{n+1}\right)^{a b}, q\right)=\sum_{k=0}^{n} \frac{n-k+1}{n+1}\binom{n+k}{n} q^{k}$, cf [55], A009766.

10 For the reader convenience we recall a definition of a tableau word. Let $T$ be a (regular shape) semistandard Young tableau. The tableau word $w(T)$ associated with $T$ is the reading word of $T$ is the sequence of entries of $T$ obtained by concatenating the columns of $T$ bottom to top consecutively starting from the first column. For example, take

$$
T=\begin{array}{cccc}
1 & 2 & 3 & 3 \\
2 & 3 & 4 & \\
3 & 4 & & \\
5 & &
\end{array} .
$$

The corresponding tableau word is $w(T)=5321432433$. By definition, a tableau word is the tableau word corresponding to some (regular shape) semistandard Young tableau. It is well-known 34 that the number of tableau subwords contained in $I_{0}$ is equal to the number of alternating sign matrices $\operatorname{ASM}(n)$.

Definition $5.15 \quad$ Denote by $\mathcal{P C} C_{n}^{\sharp}$ the quotient of the algebra $\mathcal{P C}_{n}$ by the two-sided ideal generated by the elements $\left\{u_{i} u_{j}-u_{j} u_{i}, \quad|i-j| \geq 2\right\}$.

Proposition 5.16 Dimension $\operatorname{dim} \mathcal{P C}_{n}^{\sharp}$ of the algebra $\mathcal{P} \mathcal{C}_{n}^{\sharp}$ is equal to the number of $D y c k$ paths whose ascent lengths are exactly $\{1,2, \ldots, n+1\}$.

See [55], $A 107877$ where the first few of these numbers are displayed.
Example 5.17 $\operatorname{Hilb}\left(\mathcal{P C}{ }_{5}^{\sharp}, t\right)=(1,4,12,27,48,56,54,38,20,7,1)_{t}$,
$\operatorname{Hilb}\left(\mathcal{P} C_{6}^{\sharp}, t\right)=(1,5,18,50,116,221,321,398,414,368,275,175,89,35,9,1)_{t}$, $\operatorname{dim} \mathcal{P} \mathcal{C}_{7}^{\sharp}=28612$.

Example $5.18 \quad \operatorname{Hilb}\left(\mathcal{P C}_{3}, q\right)=(1,2,3,1)_{q}, \quad \operatorname{Hilb}\left(\mathcal{P C} \mathcal{C}_{4}, q\right)=(1,3,8,12,11,6,1)_{q}$,
$\operatorname{Hilb}\left(\mathcal{P C}_{5}, q\right)=(1,4,15,35,69,91,98,70,35,10,1)_{q}$,
$\operatorname{Hilb}\left(\mathcal{P C}_{6}, q\right)=(1,5,24,74,204,435,783,1144,1379,1346,1037,628,275,85,15,1)_{q}$,
$\operatorname{Hilb}\left(\mathcal{P C}_{7}, q\right)=(1,6,35,133,461,1281,3196,6686,12472,19804,27811,33271,34685,30527$, $22864,14124,7126,2828,840,175,21,1)_{q}$.

Problem 5.19 Denote by $\mathfrak{A}_{n}$ the algebra generated by the curvature of 2 -forms of the tautological Hermitian linear bundles $\xi_{i}, 1 \leq i \leq n$, over the flag variety $\mathcal{F} l_{n}$, [54]. It is well-known [50] that the Hilbert polynomial of the algebra $\mathfrak{A}_{n}$ is equal to

$$
\operatorname{Hilb}\left(\mathfrak{A}_{n}, t\right)=\sum_{F \in \mathcal{F}(n)} t^{i n v(F)}=\sum_{F \in \mathcal{F}(n)} t^{\operatorname{maj}(F)},
$$

where the sum runs over the set $\mathcal{F}(n)$ of forests $F$ on the $n$ labeled vertices, and inv $(F)$ (resp. $\operatorname{maj}(F)$ ) denotes the inversion index (resp. the major index) of a forest $F .{ }^{11}$

Clearly that

$$
\left.\operatorname{dim}\left(\mathfrak{A}_{n}\right)_{\binom{n}{2}}\right)=\operatorname{dim}\left(\mathcal{P} \mathcal{C}_{n}\right)_{\binom{n}{2}}=\operatorname{dim}\left(H^{\star}\left(\mathcal{F} l_{n}, \mathbb{Q}\right)_{\binom{n}{2}}=1 .\right.
$$

For example,
$\operatorname{Hilb}\left(\mathcal{P C}_{6}, t\right)=(1,5,24,74,204,435,783,1144,1379,1346,1037,628,275,85,15,1)_{t}$,
$\operatorname{Hilb}\left(\mathfrak{A}_{6}, t\right)=(1,5,15,35,70,126,204,300,405,490,511,424,245,85,15,1)_{t}$,
$\operatorname{Hilb}\left(H^{\star}\left(\mathcal{F} l_{n}, \mathbb{Q}\right), t\right)=(1,5,14,29,49,71,90,101,101,90,71,49,29,14,5,1)_{t}$.
We expect that $\operatorname{dim}\left(\mathcal{P} \mathcal{C}_{n}\right)_{\binom{n}{2}-1}=\binom{n}{2} \quad$ and $\operatorname{dim}\left(\mathcal{P C}{ }_{n}\right)_{\binom{n}{2}-2}=\frac{3 n+5}{4}\binom{n+2}{3}=s(n+2,2)$, where $s(n, k)$ demotes the Stirling number of the first kind, see e.g. [55], A000914.

[^6]
## Problems

(1) Is it true that $\operatorname{Hilb}\left(\mathcal{P C}_{n}, t\right)-\operatorname{Hilb}\left(\mathfrak{A}_{n}, t\right) \in \mathbb{N}[t]$ ?

If so, as we expect, does there exist an embedding of sets $\iota: \mathcal{F}(n) \hookrightarrow \mathcal{A}_{n}$ such that $\operatorname{inv}(F)=n(\iota(F))$ for all $F \in \mathcal{F}_{n}$ ?

See Section 5.1 for definitions of the set $\mathcal{A}_{n}$ and statistics $n(T), T \in \mathcal{A}_{n}$, Definition 5.5.
(2) It is well-known that $\#\left|S T Y\left(\delta_{n}, \leq n\right)\right|=2^{\delta_{n}}=2^{\binom{n}{2}}$, where $\delta_{n}=(n-1, n-2, \ldots, 2,1), S T Y\left(\delta_{n}, \leq n\right)$ denotes the set of semistandard Young tableaux of shape $\delta_{n}$ with entries bounded by $n$,
$2^{\delta_{n}}$ stands for the set of all subsets of boxes of the staircase diagram $\delta_{n}$.
Define a "natural" bijection $\kappa: S T Y\left(\delta_{n}, \leq n\right) \longleftrightarrow 2^{\delta_{n}}$ such that the set $\kappa(M T(n))$ admits a "nice" combinatorial description. Here $M T(n)$ denotes the set of (increasing) monotone triangles, i.e. the subset of $\operatorname{STY}\left(\delta_{n}, \leq n\right)$ consisting of tableaux $T=\left(t_{i, j}\right)_{\substack{i+j \leq n+1 \\ i \geq 1, j \geq 1}}$ such that $t_{i, j} \geq t_{i-1, j+1}, \quad 2 \leq i \leq n, 1 \leq j<n$, cf [56].

Comments 5.3
One can ask a natural question :
when does noncommutative elementary polynomials $e_{1}(\mathbb{A}), \cdots, e_{n}(\mathbb{A})$ form a $q$-commuting family, i.e. $e_{i}(\mathbb{A}) e_{j}(\mathbb{A})=q e_{j}(\mathbb{A}) e_{i}(\mathbb{A}), 1 \leq i<j \leq n$ ?

Clearly that in the case of two variables one needs to necessitate the following relations

$$
e_{i} e_{j} e_{i}+e_{j} e_{j} e_{i}=q e_{j} e_{i} e_{i}+q e_{j} e_{i} e_{j}, \quad i<j
$$

Having in mind to construct a quantization, or $q$-analogue of the plactic algebra $\mathcal{P}_{n}$, one would be forced to the following relations

$$
q e_{j} e_{i} e_{j}=e_{j} e_{j} e_{i} \quad \text { and } \quad q e_{j} e_{i} e_{i}=e_{i} e_{i} e_{j} e_{i}, \quad i<j .
$$

It is easily seen that these two relation are compatible iff $q^{2}=1$. Indeed.

$$
e_{j} \underline{e_{j} e_{i} e_{j}}=q e_{j} \underline{e_{i} e_{j} e_{i}}=q^{2} e_{j} e_{j} e_{i} e_{i}, \quad \Longrightarrow \quad q^{2}=1 .
$$

In the case $q=1$ one comes to the Knuth relations ( $P L$ 1) and ( $P L 2$ ). In the case $q=-1$ one comes to the "odd" analogue of the Knuth relations, or "odd" plactic relations $\left(O P L_{n}\right)$, i.e., $\left(O P L_{n}\right)$ :

$$
u_{j} u_{i} u_{j}=-u_{j} u_{j} u_{i}, \quad \text { if } i<j \leq k \leq n, \quad \text { and } \quad u_{i} u_{j} u_{i}=-u_{j} u_{i} u_{i}, \quad \text { if } i \leq j<k \leq n .
$$

Proposition 5.20 (AK) Assume that the elements $\left\{u_{1}, \ldots, u_{n-1}\right\}$ satisfy the odd plactic relations $\left(O P L_{n}\right)$. Then the noncommutative elementary polynomials $e_{1}(U), \ldots, e_{n}(U)$ are mutually anticommute.

More generally, let $\mathcal{Q}_{\mathbf{n}}:=\left\{q_{i j}\right\}_{1 \leq i<j \leq n-1}$ be a set of parameters. Define generalized plactic algebra $\mathcal{Q} \mathcal{P}_{n}$ to be (unital) associative algebra over the ring $\mathbb{Z}\left[\left\{q_{i j}^{ \pm 1}\right\}_{1 \leq i<j \leq n-1}\right]$ generated by elements $u_{1}, \ldots, u_{n-1}$ subject to the set of relations

$$
\begin{equation*}
q_{i k} u_{j} u_{i} u_{k}=u_{j} u_{k} u_{i} \text {, if } i<j \leq k, \quad \text { and } \quad q_{i k} u_{i} u_{k} u_{j}=u_{k} u_{i} u_{j}, \quad \text { if } i \leq j<k . \tag{5.17}
\end{equation*}
$$

Proposition 5.21 Assume that $q_{i j}:=q_{j}, \forall 1 \leq i<j$.
Then the reduced generalized plactic algebra $\mathcal{Q \mathcal { P }} \overline{\mathcal{C}}_{n}$ is a free $\mathbb{Z}\left[q_{2}^{ \pm 1}, \ldots, q_{n-1}^{ \pm 1}\right]$-module of rank equals to the number of alternating sign matrices $\operatorname{ASM}(n)$. Moreover,

$$
\operatorname{Hilb}\left(\mathcal{Q P} \mathcal{C}_{n}, t\right)=\operatorname{Hilb}\left(\mathcal{P} \mathcal{C}_{n}, t\right), \quad \operatorname{Hilb}\left(\mathcal{Q} \mathcal{P}_{n}, t\right)=\operatorname{Hilb}\left(\mathcal{P}_{n}, t\right)
$$

Recall that reduced generalized plactic algebra is the quotient of the generalized plactic algebra by the two-sided ideal $J_{n}$ introduced in Definition 5.13.

## Example 5.22

(A) (Super plactic monoid, [44], [27]) Assume that the set of generators $U:=$ $\left\{u_{1}, \ldots, u_{n-1}\right\}$ is divided on two non-crossing subsets, say $Y$ and $Z, Y \cup Z=U, Y \cap Z=\emptyset$. To each element $u \in U$ let us assign the weight $w t(u)$ as follows: $w t(u)=0$, if $u \in Y$, and $w t(u)=1$ if $u \in Z$. Finally, define parameters of the generalized plactic algebra $\mathcal{Q} \mathcal{P}_{n}$ to be $q_{i j}=(-1)^{w t\left(u_{i}\right) w t\left(u_{j}\right)}$. As a result we led to conclude that the generalized plactic algebra $\mathcal{Q} \mathcal{P}_{n}$ in question coincides with the super plactic algebra $\mathcal{P S}(V)$ introduced in 44. We will denote this algebra by $\mathcal{S} \mathcal{P}_{k, l}$, where $k=|Y|, l=|Z|$. We refer the reader to papers 44] and [27] for more details about connection of the super plactic algebra and super Young tableaux, and super analogue of the Robinson-Schensted -Knuth correspondence. We are planning to report on some properties of the Cauchy kernel in the super plactic algebra elsewhere.
(B) $\quad(q$-analogue of plactic algebra)

Now let $q \neq 0, \pm 1$ be a parameter, and assume that $q_{i j}=q, \forall 1 \leq i<j \leq n-1$. This case has been treated recently in [43]. We expect that the generalized Knuth relations (5.17) are related with quantum version of the tropical/geometric RSK-correspondence (work in progress), and, probably, with a $q$-weighted version of the Robinson- Schensted algorithm, presented in 48]. Another interesting problem is to understand a meaning of $\mathcal{Q}$-plactic polynomials coming from the decomposition of the Cauchy kernels $\mathcal{C}_{n}$ and $\mathcal{F}_{n}$ in the reduced generalized plactic algebra $\mathcal{Q P} \mathcal{C}_{n}$.

### 5.2 Nilplactic algebra $\mathcal{N} \mathcal{P}_{n}$

Let $\lambda$ be a partition and $\alpha$ be a composition of the same size. Denote by $\widehat{S T Y}(\lambda, \alpha)$ the set of columns and rows strict Young tableaux $T$ of the shape $\lambda$ and content $\alpha$ such that the corresponding tableau word $w(T)$ is reduced, i.e. $l(w(T))=|T|$.

Denote by $\mathcal{B}_{n}$ the union of the sets $\widehat{S T Y}(\lambda, \alpha)$ for all partitions $\lambda$ such that $\lambda_{i} \leq n-i$ for $i=1,2, \cdots, n-1$, and all compositions $\alpha, \alpha \subset \delta_{n}$.

For example, $\left|\mathcal{B}_{n}\right|=1,2,6,25,139,1008, \cdots$, for $n=1,2,3,4,5,6, \cdots$.

## Theorem 5.23

(1) In the nilplactic algebra $\mathcal{N} \mathcal{P}_{n}$ the Cauchy kernel has the following decomposition

$$
\begin{equation*}
\mathcal{C}_{n}(\mathfrak{P}, U)=\sum_{T \in \mathcal{B}_{n}} \mathcal{K}_{T}(\mathfrak{P}) u_{w(T)} . \tag{5.18}
\end{equation*}
$$

(2) Let $T \in \mathcal{B}_{n}$ be a tableau, and assume that its bottom code is a partition. Then

$$
\mathcal{K}_{T}(\mathfrak{P})=\prod_{(i, j) \in T} p_{\{i, T(i, j)-j+1\}}
$$

Example 5.24 For $n=4$ one has $\mathcal{C}_{4}(X, U)=$
$K[0]+K[1] u_{1}+K[01] u_{2}+K[001] u_{3}+K[11] u_{12}+K[2]\left(u_{21}+u_{31}\right)+K[101] u_{13}+$
$K[02] u_{32}+K[011] u_{23}+K[3] u_{321}+K[12] u_{312}+K[21] u_{212}+$
$K[111] u_{123}+K[021] u_{323}+K[201] u_{213}+K[31] u_{3212}+$
$K[301] u_{3213}+K[22] u_{2132}+K[121] u_{3123}+K[211] u_{2123}+K[32] u_{32132}+$
$K[311] u_{32123}+K[221] u_{21323}+K[321] u_{321323}$.

### 5.3 Idplactic algebra $\mathcal{I} \mathcal{P}_{n}$

Let $\lambda$ be a partition and $\alpha$ be a composition of the same size. Denote by $\widetilde{\operatorname{STY}}(\lambda, \alpha)$ the set of columns and rows strict Young tableaux $T$ of the shape $\lambda$ and content $\alpha$ such that $l(w(T))=r l(w(T))$, i.e. the tableau word $w(T)$ is a unique tableau word of minimal length in the idplactic class of $w(T)$, cf Example 1.9.

Denote by $\mathcal{D}_{n}$ the union of the sets $\widetilde{S T Y}(\lambda, \alpha)$ for all partitions $\lambda$ such that $\lambda_{i} \leq n-i$ for $i=1,2, \cdots, n-1$, and all compositions $\alpha, l(\alpha) \leq n-1$.

For example, $\left|\mathcal{D}_{n}\right|=1,2,6,26,154,1197, \cdots$, for $n=1,2,3,4,5,6, \cdots$.

## Theorem 5.25

In the idplactic algebra $\mathcal{I P}_{n}$ the Cauchy kernel has the following decomposition

$$
\begin{equation*}
\mathcal{C}_{n}(X, Y, U)=\sum_{T \in \mathcal{D}_{n}} \mathcal{K} \mathcal{G}_{T}(X, Y) u_{w(T)} \tag{5.19}
\end{equation*}
$$

(2) Let $T \in \mathcal{D}_{n}$ be a tableau, and assume that its bottom code is a partition. Then

$$
\mathcal{K} \mathcal{G}_{T}(X, Y)=\mathcal{K}_{T}(X, Y)=\prod_{(i, j) \in T}\left(x_{i}+y_{T(i, j)-j+1}\right)
$$

Example 5.26 For $n=4$ one has $\mathcal{C}_{4}(X, U)=$
$K G[0]+K G[1] u_{1}+K G[01] u_{2}+K G[001] u_{3}+K G[11] u_{12}+K G[2]\left(u_{21}+u_{31}\right)+K G[101] u_{13}+$
$K G[02] u_{32}+K G[011] u_{23}+K G[3] u_{321}+K G[12] u_{312}+K G[21] u_{212}+$
$K G[111] u_{123}+K G[021] u_{323}+K G[201]\left(u_{313}+u_{213}\right)+K[31] u_{3212}+$
$K G[301] u_{3213}+K G[22] u_{2132}+K G[121] u_{3123}+K G[211] u_{2123}+K G[32] u_{32132}+$
$K G[311] u_{32123}+K G[221] u_{21323}+K G[321] u_{321323}$.
Theorem 5.27 For each composition $\alpha$ the key Grothendieck polynomial $K G[\alpha](X)$ is a linear combination of key polynomials $K[\beta](X)$ with nonnegative integer coefficients.

### 5.4 NilCoxeter algebra $\mathcal{N C}{ }_{n}$

Theorem 5.28 In the nilCoxeter algebra $\mathcal{N C}_{n}$ the Cauchy kernel has the following decomposition

$$
\begin{equation*}
\mathcal{C}_{n}(X, Y, U)=\sum_{w \in \mathbb{S}_{n}} \mathfrak{S}_{w}(X, Y) u_{w} . \tag{5.20}
\end{equation*}
$$

Let $w \in \mathbb{S}_{n}$ be a permutation, denote by $R(w)$ the set of all its reduced decompositions. Since the nilCoxeter algebra $\mathcal{N} \mathcal{C}_{n}$ is the quotient of the nilplactic algebra $\mathcal{N} \mathcal{P}_{n}$, the set $R(w)$ is the union of nilplactic classes of some tableau words $w\left(T_{i}\right): \quad R(w)=\bigcup C\left(T_{i}\right)$. Moreover, $R(w)$ consists of only one nilplactic class if and only if $w$ is a vexillary permutation. In general case we see that the set of compatible sequences $C R(w)$ for permutation $w$ is the union of sets $C\left(T_{i}\right)$.

Corollary 5.29 Let $w \in \mathbb{S}_{n}$ be a permutation of length $l$, then
(1) $\mathfrak{S}_{w}(X, Y)=\sum_{\mathbf{b} \in C R(w)} x_{b_{1}} \cdots x_{b_{l}}$.
(2) Double Schubert polynomial $\mathfrak{S}_{w}(X, Y)$ is a linear combination of double key polynomials $\mathcal{K}_{T}(X, Y), T \in \mathcal{B}_{n}, w=w(T)$, with nonnegative integer coefficients.

### 5.5 IdCoxeter algebras $\mathcal{I C}_{n}^{ \pm}$

Theorem 5.30 In the IdCoxeter algebra $\mathcal{I C}_{n}^{+}$with $\beta=1$, the Cauchy kernel has the following decomposition

$$
\begin{equation*}
\mathcal{C}_{n}(X, Y, U)=\sum_{w \in \mathbb{S}_{n}} \mathcal{G}_{w}(X, Y) u_{w} \tag{5.21}
\end{equation*}
$$

Theorem 5.31 In the IdCoxeter algebra $\mathcal{I C}_{n}^{-}$with $\beta=-1$, one has the following decomposition

$$
\begin{equation*}
\prod_{i=1}^{n-1}\left\{\prod_{j=n-1}^{i}\left(\left(1+x_{i}\right)\left(1+y_{j-i+1}\right)+\left(x_{i}+y_{j-i+1}\right) u_{j}\right)\right\}=\sum_{w \in \mathbb{S}_{n}} \mathcal{H}_{w}(X, Y) u_{w} \tag{5.22}
\end{equation*}
$$

A few remarks in order.
(a) The (dual) Cauchy identity (5.21) is still valid in the idplactic algebra with constrain $u_{i}^{2}=-\beta u_{i}, i=1, \ldots, n-1$.
(b) The left hand side of the identity (5.21) can be written in the following form

$$
\prod_{\substack{1 \leq i, j \leq n \\ i+j \leq n}}\left(x_{i}+y_{j}\right) \prod_{i=1}^{n-1}\left\{\prod_{j=n-1}^{i} \frac{1}{1-\left(x_{i}+y_{j-i+1}+\beta x_{i} y_{j-i+1}\right) u_{j}}\right\}
$$

Indeed, $\left(1+\beta x+x u_{i}\right)\left(1-x u_{i}\right)=1+\beta x$, since $u_{i}^{2}=-\beta u_{i}$.
Let $w \in \mathbb{S}_{n}$ be a permutation, denote by $\operatorname{IR}(w)$ the set of all decompositions in the idCoxeter algebra $\mathcal{I C}{ }_{n}$ of the element $u_{w}$ as the product of the generators $u_{i}, 1 \leq i \leq n-1$,
of the algebra $\mathcal{I C}_{n}$. Since the idCoxeter algebra $\mathcal{I C}_{n}$ is the quotient of the idplactic algebra $\mathcal{I} \mathcal{P}_{n}$, the set $I R(w)$ is the union of idplactic classes of some tableau words $w\left(T_{i}\right): I R(w)=$ $\bigcup I R\left(T_{i}\right)$. Moreover, the set of compatible sequences $I C(w)$ for permutation $w$ is the union of sets $I C\left(T_{i}\right)$.

Corollary 5.32 Let $w \in \mathbb{S}_{n}$ be a permutation of length $l$, then
(1) $\mathcal{G}_{w}(X, Y)=\sum_{\mathbf{b} \in I C(w)} \quad \prod_{i=1}^{l}\left(x_{b_{i}}+y_{a_{i}-b_{i}+1}\right)$.
(2) Double Grothendieck polynomial $\mathcal{G}_{w}(X, Y)$ is a linear combination of double key Grothendieck polynomials $\mathcal{K} \mathcal{G}_{T}(X, Y), T \in \mathcal{B}_{n}, w=w(T)$, with nonnegative integer coefficients.

## $6 \quad \mathcal{F}$-kernel and symmetric plane partitions

Let us fix natural number $n$ and $k$, and a partition $\lambda \subset\left(n^{k}\right)$. Clearly the number of such partitions is equal to $\binom{n+k}{n}$; note that in the case $n=k$ the number $\binom{2 n}{n}$ is equal to the Catalan number of type $B_{n}$.

Denote by $\mathcal{B}_{n, k}(\lambda)$ the set of semistandard Young tableaux of shape $\lambda$ filled by the numbers from the set $\{1,2, \ldots, n\}$. For a tableau $T \in \mathcal{B}_{n, k}$ set as before,

$$
n(T):=\operatorname{Card}\{(i, j) \in \lambda \mid T(i, j)=n\}
$$

and define polynomial

$$
\mathcal{B}_{n, k}(\lambda)(q):=\sum_{T \in \mathcal{B}_{n, k}(\lambda)} q^{\lambda_{1}-n(T)} .
$$

Denote by $\mathcal{B}_{n, k}:=\bigcup_{\lambda \subset\left(n^{k}\right)} \mathcal{B}_{n, k}(\lambda)$.
Lemma 6.1 ( [14], [25] ) The number of elements in the set $\mathcal{B}_{n, k}$ is equal to

$$
\#\left|\mathcal{B}_{n, k}\right|=\prod_{1 \leq i \leq j \leq k} \frac{i+j+n-1}{i+j-1}=\prod_{\substack{a \geq 0 \\ 4 a \leq 2 k-1}} \frac{\binom{n+2 k-2 a-1}{n+2 a}}{\binom{2 k-2 a-1}{2 a}}=\prod_{a \geq 0} \frac{\binom{n+2 k+1-2 a}{n}}{\binom{n+2([(k-2) / 2]-a)}{n}} .
$$

See also [55], $A 073165$ for other combinatorial interpretations of the numbers $\#\left|\mathcal{B}_{n, k}\right|$. For example, the number $\#\left|\mathcal{B}_{n, k}\right|$ is equal to the number of symmetric plane partitions fit inside the box $n \times k \times k$.

Proposition 6.2 One has

- $\#\left|\mathcal{B}_{n, n}\right|:=\operatorname{SPP}(n)=\operatorname{TSPP}(n) \times \operatorname{ASM}(n), \quad \#\left|\mathcal{B}_{n, n+1}\right|=\operatorname{TSPP}(n) \times \operatorname{ASM}(n+1)$,
where $\operatorname{TSPP}(n)$ denotes the number of totally symmetric plane partitions fit inside the $n \times$ $n \times n$-box, see e.g. [55], A005157, whereas $A S M(n)=\operatorname{TSSCPP}(2 n)$ denotes the of $n \times n$ alternating sign matrices, and $\operatorname{TSSCPP}(2 n)$ denotes the number of totally symmetric selfcomplimentary plane partitions fit inside the $2 n \times 2 n \times 2 n$-box.
- $\quad \#\left|\mathcal{B}_{n+2, n}\right|=\#\left|\mathcal{B}_{n, n+1}\right|$.

Note that in the case $n=k$ the number $\mathcal{B}_{n}:=\mathcal{B}_{n, n}$ is equal to the number of symmetric plane portions fit inside the $n \times n \times n$-box, see [55], A049505. Let us point to that in general it may happen that the number $\#\left|\mathcal{B}_{n, n+2}\right|$ does not divisible by any $\operatorname{ASM}(m), m \geq 3$. For example, $\mathcal{B}_{3,5}=4224=2^{5} \times 3 \times 11$. On the other hand, it's possible that the number $\#\left|\mathcal{B}_{n, n+2}\right|$ is divisible by $\operatorname{ASM}(n=1)$, but does not divisible by $A S M(n+2)$. For example, $\mathcal{B}_{4,6}=306735=715 \times 429$, but $306735 \nmid 7436=A S M(6)$.

Problem 6.3 Let $a$ is equal to either 0 or 1 . Construct bijection between the set $P P(n, n+a, n+a)$ of symmetric plane partitions fit inside the box $n \times n+a \times n+a \underline{\text { and }}$ and the set of pairs $(P, M)$ where $P$ is the totally symmetric plane partitions fit inside the box $n \times n \times n$ and $M$ is an alternating sign matrix of size $n+a \times n+a$.

Example 6.4 Take $n=3$. The number of partitions $\lambda \subset\left(3^{3}\right)$ is equal to 20, namely, namely, the partitions $\left\{\emptyset,(1),(2),(1,1),(3),(2,1),\left(1^{3}\right),(3,1),(2,2),\left(2,1^{2}\right),(3,2),\left(3,1^{2}\right),\left(2^{2}, 1\right),\left(3^{2}\right)\right.$, $\left.(3,2,1),\left(2^{3}\right),\left(3^{2}, 1\right),\left(3,2^{2}\right),\left(3^{2}, 2\right),\left(3^{3}\right)\right\}$, and

$$
\mathcal{B}_{3}(q):=\sum_{\lambda \subset\left(3^{3}\right)} \#\left|\mathcal{B}_{3}(\lambda)\right| q^{|\lambda|}=(1,3,9,19,24,24,19,9,3,1)=(1+q)^{3}\left(1+q^{2}\right)\left(1+5 q^{2}+q^{4}\right) .
$$

Note, however, that

$$
\sum_{\lambda \subset\left(4^{4}\right)} \#\left|\mathcal{B}_{4}(\lambda)\right| q^{|\lambda|}=(1,4,16,44,116,204,336,420,490,420,336,204,116,44,16,4,1)
$$

is an irreducible polynomial, but its value at $q=1$ is equal to $2772=66 \times 42$.
Let $\mathbf{p}=\left(p_{i, j}\right)_{1 \leq i \leq n, 1 \leq j \leq k}$ be a $n \times k$ matrix of variables.
Definition 6.5 Define the kernel $\mathcal{F}_{n, k}(\mathbf{p}, U)$ as follows

$$
\mathcal{F}_{n, k}(\mathbf{p}, U)=\prod_{i=1}^{k-1} \prod_{j=n-1}^{1}\left(1+p_{i, \overline{j-i+1}}(n) \quad u_{j}\right)
$$

where for a fixed $n \in \mathbb{N}$ and an integer $a \in \mathbb{Z}$, we set

$$
\bar{a}=\bar{a}^{(n)}:=\left\{\begin{aligned}
a, & \text { if } a \geq 1, \\
n+a-1 & \text { if } a \leq 0 .
\end{aligned}\right.
$$

For example, $\mathcal{F}_{3}(\mathbf{p}, U)=\left(1+p_{1,2} u_{2}\right)\left(1+p_{1,1} u_{1}\right)\left(1+p_{2,1} u_{2}\right)\left(1+p_{2,2} u_{1}\right)$.
In the plactic algebra $\mathcal{F} \mathcal{P}_{3,3}$ one has $\quad \mathcal{F}_{3,3}(\mathbf{p}, U)=1$
$+\left(p_{1,1}+p_{2,2}\right) u_{1}$
$+\left(p_{1,2}+p_{2,1}\right) u_{2}$
$+p_{1,1} p_{2,1} u_{11}$
$+p_{1,1} p_{2,1} u_{12}$
$+\left(p_{1,2} p_{1,1}+p_{1,2} p_{2,2}+p_{2,1} p_{2,2}\right) u_{21}$
$+p_{1,2} p_{2,1} u_{22}$
$+\left(p_{1,1} p_{1,2} p_{2,2}+p_{1,2} p_{2,2} p_{2,1}\right) u_{212}$
$+\left(p_{1,1} p_{1,2} p_{2,2}+p_{1,1} p_{2,2} p_{2,1}\right) u_{211}$
$+p_{1,1} p_{1,2} p_{2,1} p_{2,2} u_{2121}$.

Definition 6.6 Define algebra $\mathcal{P} \mathcal{F}_{n, k}$ to be the quotient of the plactic algebra $\mathcal{P}_{n}$ by the two-sided ideal $I_{n}$ generated by the set of monomials

$$
\left\{u_{i_{1}} u_{i_{2}} \cdots u_{i_{k}}\right\}, \quad 1 \leq i_{1} \leq i_{2} \leq \cdots \leq i_{k} \leq n-1
$$

Theorem 6.7

- $\operatorname{Hilb}\left(\mathcal{P F}_{n, k}, q\right)=\mathcal{B}_{n-1, k-1}(q)$,

In particular,

- The algebra $\mathcal{P \mathcal { F }}{ }_{n, n}$ has dimension equals to the number of symmetric plane partitions $S P P(n-1)$,

$$
\text { - } \quad \operatorname{Hilb}\left(\mathcal{P} \mathcal{F}_{n, k}, q\right)=q^{\frac{k n}{2}} \mathfrak{s o}_{\left(\frac{k}{2}\right)^{n}}(\underbrace{q^{ \pm 1}, \ldots, q^{ \pm 1}}_{k}, 1)
$$

where $\mathfrak{s o}_{\left(\frac{k}{2}\right)^{n}}(\underbrace{q^{ \pm 1}, \ldots, q^{ \pm 1}}_{k}, 1)$ denotes the specialization $x_{2 j}=q, x_{2 j-1}=q^{-1}, 1 \leq j \leq$ $k$, of the character $\mathfrak{s o}_{\lambda}\left(x_{1}, x_{1}^{-1} \ldots, x_{k}, x_{k}^{-1}, 1\right)$ of the odd orthogonal Lie algebra $\mathfrak{s o}(2 k+1)$ corresponding to the highest weight $\lambda=(\underbrace{\frac{k}{2}, \ldots, \frac{k}{2}}_{n})$.

- $\operatorname{deg}_{q} \operatorname{Hilb}\left(\mathcal{P} \mathcal{F}_{n, k}, q\right)=(n-1)(k-1), \quad$ and $\quad \operatorname{dim}\left(\mathcal{P} \mathcal{F}_{n, k}\right)_{(n-1)(k-1)}=1$,
- The Hilbert polynomial $\operatorname{Hilb}\left(\mathcal{P} \mathcal{F}_{n, k}, q\right)$ is symmetric (unimodal ?) polynomial in the variable $q$,
- $\operatorname{Hilb}\left(\left(\mathcal{P F}_{n, k}\right)^{a b}, q\right)=\sum_{j=0}^{k-1}\binom{n+j-2}{n-2} q^{j}$.

The key step in proofs of Lemma 6.1 and Theorem 6.5 is based on the following identity

$$
\begin{equation*}
\sum_{\lambda \subset\left(n^{k}\right)} s_{\lambda}\left(x_{1}, \ldots, x_{k}\right)=\left(x_{1} \cdots x_{k}\right)^{n / 2} \mathfrak{s o}_{\left(\frac{k}{2}\right)^{n}}\left(x_{1}, x_{1}^{-1}, \ldots, x_{k}, x_{k}^{-1}, 1\right) \tag{6.23}
\end{equation*}
$$

see e.g., [45], Ch.I, Sec.5, Ex.19, [25] and the literature quoted therein.

## Problem 6.8

Let $\Gamma:=\Gamma_{n, m}{ }^{k, \ell}=\left(n^{k}, m^{\ell}\right), n \geq m$ be a "fat hook". Find generalizations of the identity (6.21) and those listed in [17], p. 71, to the case of fat hooks, namely to find "nice" expressions for the following sums

$$
\text { - } \quad \sum_{\lambda \subset \Gamma} s_{\lambda}\left(X_{k+\ell}, \quad \sum_{\lambda \subset \Gamma} s_{\lambda}\left(X _ { k + \ell } s _ { \lambda } \left(Y_{k+\ell},\right.\right.\right.
$$

- Find "bosonic" type formulas for these sum at the limit $n \longrightarrow \infty, \ell \longrightarrow \infty, m, k$ are fixed.

Example 6.9 $\operatorname{Hilb}\left(\mathcal{P} \mathcal{F}_{2,3}, q\right)=(1,3,9,9,9,3,1)_{q}, \operatorname{dim}\left(\mathcal{P F} \mathcal{F}_{2,4}\right)=35=5 \times 7, \quad$ and $\operatorname{dim}\left(\mathcal{P} \mathcal{F}_{2,5}\right)=126=3 \times 42$
$\operatorname{Hilb}\left(\mathcal{P F}_{3,5}, q\right)=(1,4,16,44,81,120,140,120,81,44,16,4,1)_{q}, \quad \operatorname{dim}\left(\mathcal{P} \mathcal{F}_{3,5}\right)=672=16 \times 42$, $\operatorname{Hilb}\left(\mathcal{P F}_{5}, q\right)=(1,4,16,44,116,204,336,420,490,420,336,204,116,44,16,4,1)_{q}, \operatorname{dim}\left(\mathcal{P F} \mathcal{F}_{5,5}\right)=$ $2772=66 \times 42$.

## Proposition 6.10

$$
\text { - } \quad \operatorname{Hilb}\left(\mathcal{P F}_{3, n}, q\right)=\sum_{k=0}^{2 n}\binom{n}{\left[\frac{k}{2}\right]}\binom{n}{\left[\frac{k+1}{2}\right]} q^{k}, \quad \operatorname{dim}\left(\mathcal{P} \mathcal{F}_{3, n}\right)=\binom{2 n-1}{n} .
$$

Therefore, $\operatorname{Hilb}\left(\mathcal{P F}_{3, n}, q\right)$ is equal to the generating function for the number of symmetric Dyck paths of semilength $2 n-1$ according to the number of peaks, see [55], A088855.

- $\operatorname{dim}\left(\mathcal{P} \mathcal{F}_{4, n+1}\right)=2^{n}$ Cat $_{n+1}$, if $n \geq 4$.

For example, $\quad \operatorname{dim}\left(\mathcal{P} \mathcal{F}_{4,7}\right)=27456=64 \times 429, \quad \operatorname{Hilb}\left(\mathcal{P F}_{4,7}, q\right)=$ $(1,6,36,146,435,1056,2066,3276,4326,4760,4326,3276,2066,1056,435,146,36,6,1)$. Several interesting interpretations of these numbers are given in [55], A003645.

## Theorem 6.11

- (Symmetric plane partitions and Catalan numbers)

$$
\#\left|\mathcal{B}_{4, n}\right|=\frac{1}{2} C a t_{n+1} \times C a t_{n+2} .
$$

- (Symmetric plane partitions and alternating sign matrices)
$\#\left|\mathcal{B}_{n+3, n}\right|=\frac{1}{2} \quad \operatorname{TSPP}(n+1) \times \operatorname{ASM}(n+1)=\frac{1}{2} \#\left|\mathcal{B}_{n+1, n+1}\right|$.
- (Plane partitions and alternating sign matrices invariant under a half-turn)

$$
\#|P P(n)|=A S M(n) \times A S M H T(2 n)
$$

where $P P(n)$ denotes the number of plane partitions fit inside an $n \times n \times n$ box; $A S M H T(2 n)$ denotes the number of alternating sign $2 n \times 2 n$-matrices invariant under a half-turn, see e.g. [56], [26], [49], [3], [55], A005138.

- (Plactic decomposition of the $\mathcal{F}_{n}$-kernel)

$$
\mathcal{F}_{n, m}=\sum_{T} u_{T} U_{T}\left(\left\{p_{i j}\right\}\right)
$$

where summation runs over the set of semistandard Young tableaux $T$ of shape $\lambda \subset(n)^{m}$ filled by the numbers from the set $\{1, \ldots, m\}$.

- $\quad U_{T}\left(\left\{p_{i j}=1, \forall i, j\right\}\right)=\operatorname{dim} V_{\lambda^{\prime}}^{\mathfrak{g l}(m)}$, where $\lambda$ denotes the shape of a tableau $T$, and $\lambda^{\prime}$ denotes the conjugate/transpose of a partition $\lambda$.

## 7 Appendix

### 7.1 Some explicit formulas for $n=4$ and compositions $\alpha$ such that $\alpha_{i} \leq n-i$ for $i=1,2, \cdots$.

(1) Schubert and $(-\beta)$-Grothendieck polynomials $\mathcal{G}^{-}[\alpha]:=\mathcal{G}^{-\beta}[\alpha]$ for $n=4$

```
    \(\mathfrak{S}_{1234}=\mathfrak{S}[0]=1=\mathcal{G}^{-}[0]\),
\(\mathfrak{S}_{2134}=\mathfrak{S}[1]=x_{1}=\mathcal{G}^{-}[1]\),

```

Theorem 7.1 (cf [30], Section 5.5)
Each Schubert polynomial is a linear combination of $(-\beta)$ - Grothendieck polynomials with nonnegative coefficients from the ring $\mathbb{N}[\beta]$.

## (2) Key and reduced key polynomials.

$K[0]=1=\widehat{K}[0]$,
$K[1]=x_{1}=\widehat{K}[1]$,
$K[01]=x_{1}+x_{2}, \widehat{K}[01]=x_{2}$,
$K[001]=x_{1}+x_{2}+x_{3}, \widehat{K}[001]=x_{3}$,
$K[2]=x_{1}^{2}=\widehat{K}[2]$,
$K[11]=x_{1} x_{2}=\widehat{K}[11]$,
$K[101]=x_{1} x_{2}+x_{1} x_{3}, \widehat{K}[101]=x_{1} x_{3}$,
$K[02]=x_{1}^{2}+x_{1} x_{2}+x_{2}^{2}, \widehat{K}[02]=x_{1} x_{2}+x_{2}^{2}$,
$K[011]=x_{1} x_{2}+x_{1} x_{3}+x_{2} x_{3}, \widehat{K}[011]=x_{2} x_{3}$,
$K[3]=x_{1}^{3}=\widehat{K}[3]$,
$K[21]=x_{1}^{2} x_{2}=\widehat{K}[21]$,
$K[111]=x_{1} x_{2} x_{3}=\widehat{K}[111]$,
$K[12]=x_{1}^{2} x_{2}+x_{1} x_{2}^{2}, \widehat{K}[12]=x_{1} x_{2}^{2}$,
$K[021]=x_{1}^{2} x_{2}+x_{1}^{2} x_{3}+x_{1} x_{2}^{2}+x_{2}^{2} x_{3}+x_{1} x_{2} x_{3}, \widehat{K}[021]=x_{1} x_{2} x_{3}+x_{2}^{2} x_{3}$,
$K[201]=x_{1}^{2} x_{2}+x_{1}^{2} x_{3}, \widehat{K}[201]=x_{1}^{2} x_{3}$,
$K[31]=x_{1}^{3} x_{2}=\widehat{K}[31]$,
$K[22]=x_{1}^{2} x_{2}^{2}=\widehat{K}[22]$,
$K[211]=x_{1}^{2} x_{2} x_{3}=\widehat{K}[211]$,
$K[301]=x_{1}^{3} x_{2}+x_{1}^{3} x_{3}, \widehat{K}[301]=x_{1}^{3} x_{3}$,
$K[121]=x_{1}^{2} x_{2} x_{3}+x_{1} x_{2}^{2} x_{3}, \widehat{K}[121]=x_{1} x_{2}^{2} x_{3}$,
$K[32]=x_{1}^{3} x_{2}^{2}=\widehat{K}[32]$,
$K[311]=x_{1}^{3} x_{2} x_{3}=\widehat{K}[311]$,
$K[221]=x_{1}^{2} x_{2}^{2} x_{3}=\widehat{K}[221]$,
$K[321]=x_{1}^{3} x_{2}^{2} x_{3}=\widehat{K}[321] ;$
Note that if $n=4$, then $\mathfrak{S}[\alpha]=K[\alpha]$ for all $\alpha \subset \delta_{4}$, except $\alpha=(101)$ in which $\mathfrak{S}[101]=K[2]+K[101]$.

Theorem 7.2 (cf [39], the case $\beta=-1$ )
Each double $\beta$-Grothendieck polynomials is a linear combination of double key polynomials with the coefficients from the ring $\mathbb{N}[\beta]$.

Let us remind that the total number of double key polynomials is equal to the number of alternating sign matrices. We expect that the interrelations between double key polynomials which follow from the structure of the plactic algebra $\mathcal{P C}_{n}$, see Section 5.1, can be identified with the graph corresponding to the MacNeile completion of the poset associated with the Bruhat order on the symmetric group $\mathbb{S}_{n}$, see Section 8.2 for a definition of the MacNeile completion. It is an interesting problem to describe interrelation graph associated with the (rectangular) key polynomials corresponding to the Cauchy kernel for the algebra $\mathcal{P} \mathcal{F}_{n, m}$.

$$

$\mathcal{K} \mathcal{N}_{121}^{(a=1, b=1, c, r)}(1)=31+112 c+168 c^{2}+124 c^{3}+44 c^{4}+6 c^{5}+\left(60+176 c+195 c^{2}+93 c^{3}+\right.$ $\left.16 c^{4}\right) r+\left(38+85 c+61 c^{2}+14 c^{3}\right) r^{2}+\left(8+12 c+4 c^{2}\right) r^{3}$.

Problem 7.3 Let $n \geq k \geq 0$ be integers, consider permutation $w_{n, k}:=[k, k-1, \ldots 1, n, n-$ $1, n-2, \ldots, k+1] \in \mathbb{S}_{n}$. Give combinatorial interpretations of polynomials $L_{n, k}(\alpha, \beta, \gamma):=$

Conjecture 7.4 Set $d:=\gamma-1$.

- For any permutation $w \in \mathbb{S}_{n}, \mathcal{K N}_{w}^{(\beta, \alpha=1, \gamma=d-1)}(1)$ is a polynomial in $\beta$ and $d$ with non-negative coefficients.
- The polynomial $L_{n}(d)$ has non-negative coefficients, and polynomial $L_{n}(d)+d^{n}$ is symmetric and unimodal.
- $\quad L_{n, 1}(\alpha=1, \beta, d) \in d \mathbb{N}[\beta, d]$.
- $L_{n, 1}(\alpha, \beta=0, d) \in d^{n-1}(\alpha+d) \mathbb{N}[\alpha, d]$,
$L_{n, 1}(\alpha=1, \beta=0, d=1)=2 \operatorname{Sch}_{n+1}, L_{n, 1}(\alpha=0, \beta=0, d=2)=2^{n} S^{S c h} h_{n+1} \quad($ see [55], A156017 for a combinatorial interpretation of these numbers),
where $S_{n}$ denotes the $n$-th Schröder number, see e.g. [55], A001003.
- $\quad L_{n, 1}(\alpha=0, \beta=t-1, \gamma) \in \mathbb{N}[t, \gamma]$,
$L_{n, 1}(\alpha=0, \beta=-1, \gamma=1)$ is equal to the number of Dyck $(n+1)$-paths (see [55], A000108) in which each up step ( $U$ ) not at ground level is colored red $(R)$ or blue ( $B$ ), [55], A064062,

Note that the number $2 S c h_{n}$ known also as Large Schrödeder number, see e.g. [55], A006318.
For example,
$L_{3,1}(\alpha=1, \beta, d)=d\left(\beta^{2}+5 \beta d+4 \beta^{2} d+5 d^{2}+14 \beta d^{2}+6 \beta^{2} d^{2}+\beta^{3} d^{2}+10 d^{3}+12 \beta d^{3}+3 \beta^{2} d^{3}+\right.$ $\left.6 d^{4}+3 \beta d^{4}+d^{5}\right), L_{7,1}(1,1, d)=d(1,27,260,1245,3375,5495,5494,3375,1245,260,27,1)_{d}$, $L_{7,1}(\alpha, \beta=0, d)=d^{6}(\alpha+d)(1+\alpha+d)\left(1+14 \alpha+36 \alpha^{2}+14 \alpha^{3}+\alpha^{4}+14 d+72 \alpha d+42 \alpha^{2} d+\right.$ $\left.4 \alpha^{3} d+36 d^{2}+42 \alpha d^{2}+6 \alpha^{2} d^{2}+14 d^{3}+4 \alpha d^{3}+d^{4}\right)$,
$L_{7,1}(\alpha=0, \beta=t-1, \gamma=1)=(14589,39446,39607,18068,3627,246,1)_{t}$
We expect a similar conjecture for polynomials $L_{n, k}(\alpha=1, \beta=1, \gamma), k \geq 1$.

### 7.2 MacMeille completion of a partially ordered set 12

Let $(\Sigma, \leq)$ be a partially ordered set (poset for short) and $X \subseteq \Sigma$. Define

- The set of upper bounds for $X$, namely,

$$
X^{u p}:=\{z \in \Sigma \mid x \leq z \quad \forall x \in X\}
$$

- The set of lower bounds for $X$, namely,

$$
X^{l o}:=\{z \in \Sigma \mid z \leq x \quad \forall x \in X\}
$$

- A poset $(\mathcal{M} \mathcal{N}(\Sigma), \leq)$, namely,

$$
\mathcal{M N}(\Sigma):=\{\mathcal{M N}(X) \mid X \subseteq \Sigma\}, \quad \text { where } \quad \mathcal{M N}(X):=\left(X^{u p}\right)^{l o}
$$

Clearly, $\quad X \subseteq \mathcal{M} \mathcal{N}(X)$ and $\mathcal{M N}(\mathcal{M N}(X))=\mathcal{M N}(X)$,

- A map $\kappa: \Sigma \longrightarrow \mathcal{M} \mathcal{N}(\Sigma)$, namely, $\kappa(X)=\mathcal{M} \mathcal{N}(X), \quad X \subseteq \Sigma$.

## Proposition 7.5

- The map $\kappa$ is an embedding, that is for $X, Y \subseteq \Sigma$,

$$
X \leq Y \quad \text { if and only if } \kappa(X) \subseteq \kappa(Y)
$$

- Poset $(\mathcal{M N}(\Sigma), \leq)$ is a lattice, called the MacNeille completion of poset $(\Sigma, \leq)$.

[^7]
## Proposition 7.6 ([59])

Let $(\Sigma, \leq)$ be a poset. $\quad$ Then there is a poset $(L, \leq)$ and a map $\kappa: \Sigma \longrightarrow L$ such that
(1) $\kappa$ is an embedding,
(2) $(L, \leq)$ is a complete lattice ${ }^{13}$,
(3) For each element $a \in L$ one has
(a) $\mathcal{M N}(\{x \in \Sigma \mid \kappa(x) \leq a\})=\{x \in \Sigma \mid \kappa(x) \leq a\}$,
(b) $\quad a=\bigvee\{\kappa(x) \mid x \in \Sigma, \kappa(x) \leq a\}$.

Moreover, the pair $(\kappa,(L, \leq))$ is defined uniquely up to an order preserving isomorphism.
Therefore, the lattice $(L, \leq)$, is an order isomorphic to the MacNeille completion $\mathcal{M N}(\Sigma)$ of a poset $\Sigma$.

## Problem 7.7

Let $\Sigma$ be a (finite) graded poset ${ }^{14}$, denote by

$$
r_{\Sigma}(t):=\sum_{a \in \Sigma} t^{r(a)}
$$

the rank generating function of a poset $\Sigma$. Here $r(a)$ denotes the rank/degree of an element $a \in \Sigma$.

Describe polynomial $\quad r_{\mathcal{M N}(\Sigma)}(t)$.

In the present paper we are interesting in properties of the MacNeille completion of the Bruhat poset $\mathcal{B}_{n}=\mathcal{B}\left(\mathbb{S}_{n}\right)$ corresponding to the symmetric group $\mathbb{S}_{n}$. Below we briefly describe a construction of the MacNeille completion $L_{n}\left(\mathbb{S}_{n}\right):=\mathcal{M} \mathcal{N}_{n}\left(\mathcal{B}_{n}\right)$ follow [28], and [57], v. 2, p. 552 , d.

Let $w=\left(w_{1} w_{2} \ldots w_{n}\right) \in \mathbb{S}_{n}$, associate wit $w$ a semistandard Young tableaux $T(w)$ of the staircase shape $\delta_{n}=(n-1, n-2, \ldots, 2,1)$ filled by integer numbers from the set $[1, n]:=$ $\{1,2, \ldots, n\}$ as follows :
the $i$-th row of of $T(w)$, denoted by $R_{i}(w)$, consists of the numbers $w_{1}, \ldots, w_{n-i+1}$ in increasing order. Clearly the tableaux $T(w)=\left[T_{i, j}(w)\right]_{1 \leq i<j \leq n-1}$ obtained in such a manner, satisfies the so-called monotonic and flag conditions, namely,
(1) (monotonic conditions) $T_{1, i} \geq T_{2, i-1} \geq \cdots \geq T_{i, 1}, i=1, \ldots, n-1$,
(2) (flag conditions) $\quad R_{1}(w) \supset R_{2}(w) \supset \cdots \supset R_{n-1}(w)$.

Denote by $L\left(\mathbb{S}_{n}\right)$ the subset of the set of all Young tableaux $T \in \operatorname{STY}\left(\delta_{n} \leq n\right)$ consisting of that $T$ which satisfies the monotonicity conditions (1). The set $L\left(\mathbb{S}_{n}\right)$ has the natural poset structure denoted by ${ }^{\prime \prime} \geq{ }^{\prime \prime}$, and defined as follows: if $T^{(1)}=\left[t_{i j}^{(1)}\right]_{1 \leq i<j \leq n-1}$ and $T^{(2)}=\left[t_{i j}^{(2)}\right]_{1 \leq i<j \leq n-1}$ belong to the set $L\left(\mathbb{S}_{n}\right)$, then by definition

$$
T^{(1)} \geq T^{(2)} \text { if and only if } t_{i j}^{(1)} \geq t_{i j}^{(2)} \text { for all } 1 \leq i<j \leq n-1
$$

[^8]It is clearly seen that the set $L\left(\mathbb{S}_{n}\right)$ is closed under the following operations

- (meet $\left.T^{(1)} T^{(2)}\right) \quad \bigwedge\left(T^{(1)}, T^{(2)}\right):=T^{(1)} \bigwedge T^{(2)}=\left[\min \left(t_{i, j}^{(1)}, t_{i, j}^{(2)}\right)\right]$,
- (join $\left.T^{(1)} T^{(2)}\right) \quad \bigvee\left(\left(T^{(1)}, T^{(2)}\right):=T^{(1)} \bigvee T^{(2)}=\left[\max \left(t_{i, j}^{(1)}, t_{i, j}^{(2)}\right)\right]\right.$.

## Theorem 7.8 ([28])

The poset $L\left(\mathbb{S}_{n}\right)$ is a complete distributive lattice with number of vertices equals to the number $A S M(n)$ that is the number of alternating sigh matrices of size $n \times n$. Moreover, the lattice $L\left(\mathbb{S}_{n}\right)$ is order isomorphic to the MacNeille completion of the Bruhat poset $\mathcal{B}_{n}$.

Indeed it is not difficult to prove that the set of all monotonic triangles obtained by applying repeatedly operation $\bigvee(=$ meet $)$ to the set $\left\{T(w), w \in \mathbb{S}_{n}\right.$ of triangles corresponding to all elements of the symmetric group $\mathbb{S}_{n}$, coincides with the set of all monotonic triangles $L\left(\mathbb{S}_{\propto}\right.$. The natural map $\kappa: \mathbb{S}_{n} \longrightarrow L\left(\mathbb{S}_{n}\right.$ is obviously embedding, and all other conditions of Proposition 7.2 are satisfied. Therefore $L\left(\mathbb{S}_{n}\right)=\mathcal{M} \mathcal{N}\left(\mathcal{B}_{n}\right.$.the fact that the lattice $L\left(\mathbb{S}_{n}\right.$ is a distributive one follows from the well-known identity

$$
\left.\max (x, \min (y, z))=\min (\max (x, y), \max (x, z)), \quad x, y, z \in_{\geq 0}^{\mathbb{R}}\right)^{3} .
$$

In the lattice $L\left(\mathbb{S}_{n}\right.$ this identity can be written in the following forms

$$
\begin{aligned}
& T^{(1)} \bigvee\left(T^{(2)} \bigwedge T^{(3)}\right)=\left(T^{(1)} \bigwedge T^{(2)}\right) \bigvee\left(T^{(1)} \bigwedge T^{(3)}\right) \\
& T^{(1)} \bigwedge\left(T^{(2)} \bigvee T^{(3)}\right)=\left(T^{(1)} \bigvee T^{(2)}\right) \bigwedge\left(T^{(1)} \bigvee T^{(3)}\right)
\end{aligned}
$$

Finally the fact that the cardinality of the lattice $L\left(\mathbb{S}_{n}\right)$ is equal to the number $A S M(n)$ had been proved by A. Lascoux and M.-P. Schützenberger [28].

If $T=\left[t_{i j}\right] \in L\left(\mathbb{S}_{n}\right)$, define rank of $T$, denoted by $r(T)$, as follows:

$$
r(T)=\sum_{1 \leq i<j \leq n-1} t_{i j}-\binom{n}{3}
$$

It had been proved by C. Ehresmann [6] that

- $\quad v \leq w$ with respect to the Bruhat order in the symmetric group $\mathbb{S}_{n}$ if and only if $T_{i, j}(v) \leq T_{i, j}(w)$ for all $1 \leq i<j \leq n-1$.

It follows from an improved tableau criterion for Bruhat order on the symmetric group [2] that 15

15 It has been proved in [2], Corollary 5, that the Ehresmann criterion stated above is equivalent to either the criterion

$$
T_{i, j}^{(1)} \leq T_{i, j}^{(2)} \text { for all } j \text { such that } w_{j}>w_{j+1} \text { and } 1 \leq i \leq j,
$$

or that

$$
T_{i, j}^{(1)} \leq T_{i, j}^{(2)} \text { for all } j \in\{1,2, \ldots, n-1\} \backslash\left\{k \mid v_{k}>v_{k+1}\right\} \text { and } 1 \leq i \leq j .
$$

- The length $\ell(w)$ of a permutation $w \in \mathbb{S}_{n}$ can be computed as follows

$$
\ell(w)=r(T(w))-\sum_{(i, j) \in I(w)}(j-i-1)
$$

where $I(w):=\left\{(i, j) \mid 1 \leq i<j \leq n, w_{i}>w_{j}\right\}$ denotes the set of inversions of permutation $w$; a detailed proof can be found in [24].

For example, consider permutation $w=[4,6,2,7,5,1,3]$. Then the code $c(w)$ of $w$ is equal to $c(w)=(3,4,1,3,2)$, and $w$ has the length $\ell(w)=13$. The corresponding Young tableau or monotonic triangle displayed below

$$
T(w)=\left[\begin{array}{cccccc}
1 & 2 & 4 & 5 & 6 & 7 \\
2 & 4 & 5 & 6 & 7 & \\
2 & 4 & 6 & 7 & & \\
2 & 4 & 6 & & & \\
4 & 6 & & & & \\
4 & & & & &
\end{array}\right]
$$

Wherefore, $\quad r(T(w))=|T(w)|-\binom{7}{3}=94-56=38$. On the other hand, the inversion set $I(w)=\{(1,3),(1,6),(1,7),(2,3),(2,5),(2,6),(2,7),(3,6),(4,5),(4,6),(4,7),(5,6),(5,7)\}$, hence $\sum_{(i, j) \in I(w)}(j-i-1)=10+9+2+3+1=25$ and $\ell(w)=38-25=13$, as it should be.

It is easily seen that the polynomial $r_{\mathcal{M N}_{n}}(t)$ is symmetric and $\operatorname{deg}\left(r_{\mathcal{M N}_{n}}(t)\right)=\binom{n+1}{3}$, For example,
$r\left(\mathcal{M N}_{3}\right)=(1,2,1,2,1), r\left(\mathcal{M N}_{4}\right)=(1,3,3,5,6,6,6,5,3,3,1)$, $r\left(\mathcal{M N}_{5}\right)=(1,4,6,10,16,20,27,34,37,40,39,40,37,34,27,20,16,10,6,4,1) ;$
$\left.r\left(\mathbb{S}_{3} \subset \mathcal{M} \mathcal{N}_{3}\right)=(1,2,0,2,1), \quad r\left(\mathbb{S}_{4} \subset \mathcal{M} \mathcal{N}_{4}\right)=(1,3,1,4,2,2,2,4,1,3,1)\right)$, $r\left(\mathbb{S}_{5} \subset \mathcal{M N}_{5}\right)=(1,4,3,6,7,6,4,10,6,10,6,10,6,10,4,6,7,6,3,4,1)$.

## Conjecture 7.9

- The number Coef $f_{\left[\binom{n+1}{3} / 2\right]} r_{\mathcal{M N}_{n}}(t)$ is a divisor of the number $\operatorname{ASM}(n)$;

[^0]:    ${ }^{1}$ See e.g. wiki/Robinson-Schensted _correspondence.
    ${ }^{2}$ If $\mathbb{A}=\{1<2<\ldots<n\}$, the elements of the algebra $\mathcal{P}(\mathbb{A})$ can be identified with semistandard Young tableaux. It was discovered by D. Knuth [21] that modulo Knuth equivalence the equivalence classes of semistandard Young tableaux form an algebra, and he has named this algebra by tableaux algebra. It is easily seen that the tableaux algebra introduced by D. Knuth is isomorphic to the algebra introduced by M.-P. Schützenberger 53.

[^1]:    ${ }^{3}$ Let us stress that conditions necessary and sufficient to assure the commutativity of noncommutative elementary polynomials for the number of variables equals $n=2$ and $n=3$ turn out to be weaker then that listed in 7

[^2]:    ${ }^{4}$ Clearly that after rescaling parameters $\alpha, \beta$ and $\gamma$ one can assume that $h=1$. However, see e.g. [20], Section 5 , the parameter $h$ plays important role in the study of different specializations of the variables $x_{i}, 1 \leq i \leq n-1$ and parameters $\alpha, \beta$ and $\gamma<$

[^3]:    ${ }^{5}$ Remind that by the name a family of Hecke's type elements we mean a set of elements $\left\{e_{1}, \cdots, c_{n}\right\}$ such that

    - (Hecke type relations) $\quad e_{i}^{2}=A e_{i}+B, A, B$ are parameters,
    - (Coxeter relations)

    $$
    c_{i} c_{j}=c_{j} c_{i}, \quad \text { if } \quad|i-j| \geq 2, \quad e_{i} e_{j} e_{i}=e_{j} e_{i} e_{j}, \quad \text { if } \quad|i-j|=1
    $$

[^4]:    ${ }^{7}$ In the case $\beta=-1$ divided difference operators $D_{i}:=\partial_{i}\left(x_{i}-x_{i} x_{i+1}\right)$ [37], formula (6), had been used by A.Lascoux to describe the transition on Grothendieck polynomials, i.e. stable decomposition of any Grothendieck polynomial corresponding to a permutation $w \in \mathbb{S}_{n}$. into a sum of Grasmannian ones corresponding to a collection of Grasmannin permutations $v_{\lambda} \in \mathbb{S}_{\infty}$, see 37] for details. The above mentioned operators $D_{i}$ had been used in [37] to construct a basis $\Omega_{\alpha} \mid \alpha \in \mathbb{Z}_{\geq 0}$ that deforms the basis which is built up from the Demazure ( known also as key) polynomials. Therefore polynomials $K G[\alpha](X ; \beta=-1)$ coincide with those introduced by A. Lascoux in 37.
    In [51] the authors give a conjectural construction for polynomials $\Omega_{\alpha}$ based on the use of extended Kohnert moves, see e.g. [45], Appendix by N. Bergeron, for definition of the Kohnert moves. We state Conjecture that

    $$
    J_{\alpha}^{(\beta)}=K G[\alpha](X ; \beta),
    $$

    where polynomials $J_{\alpha}^{\beta)}$ are defined in [51] using the $K$-theoretic versions of the Kohnert moves. For $\beta=-1$ this Conjecture has been stated in [51. It seems an interesting problem to relate the $K$-theoretic Kohnert moves with certain moves of $1^{\prime} s$ introduced in 8].

[^5]:    ${ }^{8}$ By definition, a parameter assumed to be belongs to the center of the algebra in question
    9 The relation (4.13) between parameters $a, b, c, e, h$ defines a rational four dimensional hypersurface. Its open chart $\{e h \neq 0\}$ contains, for example, the following set (cf 37]): $\left\{a=p_{1} p_{4}-p_{2} p_{3}, b=\right.$ $\left.p_{2} p_{3}, c=p_{1} p_{4}, e=p_{1} p_{3}, h=p_{2} p_{4}\right\}$, where $\left(p_{1}, p_{2}, p_{3}, p_{4}\right)$ are arbitrary parameters. However the points $\left(-b, a+b+c, c, 1,(a+c)(b+c), \quad(a, b, c) \in \mathbb{N}^{3}\right\}$ do not belong to this set

[^6]:    ${ }^{11}$ For the readers convenience we recall definitions of statistics $\operatorname{inv}(F)$ and $\operatorname{maj}(F)$. Given a forest $F$ on $n$ labeled vertices, one can construct a tree $T$ by adding a new vertex (root) connected with the maximal vertices in the connected components of $F$.

    The inversion index $\operatorname{inv}(F)$ is equal to the number of pairs $(i, j)$ such that $1 \leq i<j \leq n$, and the vertex labeled by $j$ lies on the shortest path in $T$ from the vertex labeled by $i$ to the root.

    The major index $\operatorname{maj}(F)$ is equal to $\sum_{x \in \operatorname{Des}(F)} h(x)$; here for any vertex $x \in F, h(x)$ is the size of the subtree rooted at $x$; the descent set $\operatorname{Des}(F)$ of $F$ consists of the vertices $x \in F$ which have the labeling strictly greater than the labeling of its child.

[^7]:    ${ }^{12}$ For the reader convenience we review a definition and basic facts concerning the MacNeille completion of a poset, see for example, notes by E.Turunen on web-site
    math.tut.fi/ eturunen/AppliedLogics007/Mac1.pdf

[^8]:    ${ }^{13}$ That is every subset of $L$ has a meet and join, see e.g. [57], v.1, p.249.
    ${ }^{14}$ See e.g. 57], v.1, p. 244, or
    en.wikipedia.org/wiki/Graded_poset.
