- Introduction
- Inclusive LEP-LHC Higgs (ILLH) scenario
- ILLH @MSSM and NMSSM
- Collider analysis and results
- Updated analysis (in progress)
- Summary

Introduction

- A Standard Model like Higgs particle has been found by the ATLAS & CMS collaboration of the LHC experiment with $m_h \simeq 125$ GeV.
- Evidence of this particle in multiple channels.
- The observed rates of this particle are compatible with the SM prediction.

- Higgs couplings are not yet measured very precisely
- With future LHC run and possibly at ILC the couplings will be measured more precisely => constrain several scenarios beyond the SM / or give a possible direction to new physics.

Can MSSM accommodate 125 GeV Higgs boson ?

- It seems that the observed 125 GeV Higgs like particle agrees well with prediction of MSSM.
- In MSSM, the large quadratic divergence in m_h^2 due to top quark loop is cancelled by the scalar partner of top quarks (called stop \tilde{t}_i , with i = 1, 2).
- Stop sector plays a crucial role in determining the Higgs mass

 the
 experimental determination of the stop properties is crucial to understand the
 nature of SUSY protecting the Higgs mass at EW scale.
- So far LHC has not seen any evidence of SUSY particles, only lower bounds have been put on different SUSY particles.
- Limits on gluino (\tilde{g}) and squarks (\tilde{q}) currently stands at about 1.5 TeV for $m_{\tilde{g}} \simeq m_{\tilde{q}}$ and about 1.2 TeV for $m_{\tilde{g}} \ll m_{\tilde{q}}$.

*Only a selection of the available mass limits on new states or phenomena is shown. All limits quoted are observed minus 1 or theoretical signal cross section uncertainty.

 superparticles responsible for cancellation of quadratic divergence in Higgs mass are the third generation squarks, can be comparatively light to cure the fine-tuning problem of SM.

$$\begin{array}{lll} m_h^2 &\simeq & m_Z^2 \cos^2 2\beta + \frac{3}{4\pi^2} \frac{m_t^4}{v^2} \left(\log \frac{M_S^2}{m_t^2} + \frac{X_t^2}{M_S^2} (1 - \frac{X_t^2}{12M_S^2}) \right) \\ M_S &= & \sqrt{m_{\tilde{t}_1} m_{\tilde{t}_2}} \\ X_t &\equiv & A_t - \mu \cot \beta \end{array}$$

- *A_t* : the trilinear Higgs-stop coupling.
- $m_h \Longrightarrow$ heavier for larger tan β or M_S .
- For a given M_S , m_h reaches maximum when $X_t = \sqrt{6}M_S$ so-called m_h^{max} scenario.
- Lighter stop/sbottom : large stop/sbottom tri-linear couplings.

• Light third generation scenario has an extremely attractive prospect for both the theorists and the experimentalists

Did LEP give us any hint about Higgs ?

- At LEP, Higgs boson is searched in $e^+e^-
 ightarrow ZH$ channel.
- Combined analysis of four LEP experiments: $M_h > 114.4 \text{ GeV} @ 95\% \text{ C.L.}$

- Parameter: $\zeta \equiv \begin{pmatrix} g_{HZZ}^{BSM} \\ g_{HZZ}^{M} \end{pmatrix} = \sin(\beta \alpha)$ (α : Higgs mixing angle, tan β : ratio of VEVs)
- A mild excess (~ 2.3 σ) of Higgs-like events $e^+e^- \rightarrow Zh$ with a mass near 98 GeV.

- Both LEP and LHC events can be explained simultaneously in MSSM, and NMSSM.
- MSSM: Five Higgses : h^0 , H^0 , A^0 , H^{\pm} .
- At tree level, M_A and tan β controls the MSSM Higgs sector.
- Higgs couplings to gauge bosons and fermions are functions of β and α .
- W^+W^-H , HZZ, ZAh, $W^{\pm}H^{\mp}h$, $ZW^{\pm}H^{\mp}h$ and $\gamma W^{\pm}H^{\mp}h \propto \cos(\beta \alpha)$.
- W^+W^-h , hZZ, ZAH, $W^{\pm}H^{\mp}H$, $ZW^{\pm}H^{\mp}H$ and $\gamma W^{\pm}H^{\mp}H \propto \sin(\beta \alpha)$.
- decoupling : $M_A \ge 300 \text{ GeV}$ and $\cos^2(\beta \alpha) \to 0 \implies \sin^2(\beta \alpha) \to 1$.
- In decoupling limit : One can interpret the newly observed state at 125 GeV as the light CP even Higgs boson with SM like couplings.
- non-decoupling : $M_h \sim M_A \sim M_H \sim M_Z$ or $\sin^2(\beta \alpha) \rightarrow 0 \Longrightarrow \cos^2(\beta \alpha) \rightarrow 1$.
- This would mean larger coupling strength of H with the SM gauge bosons.
- We may explore the possibility of M_H ~ 125 GeV, instead of h as the discovered new resonance.
- *H* behaves like $h_{\rm SM}$ and *h* has weaker couplings to W/Z.

- We generate approximately 70 million random points in the following combined range of parameters:
- We consider $m_t^{\text{pole}} = 173.3 \pm 2.8 \text{ GeV}.$

$$\begin{aligned} 3 < \tan \beta < 5.5, \ 0.085 < M_A < 0.2 \text{ TeV}, \ 0.3 \text{ TeV} < \mu < 12 \text{ TeV}, \\ 0.05 \text{ TeV} < M_1, M_2 < 1.5 \text{ TeV}, \ 0.9 \text{ TeV} < M_3 < 3 \text{ TeV}, \\ -8 \text{ TeV} < A_t < 8 \text{ TeV}, \ -3 \text{ TeV} < A_b, \ A_\tau < 3 \text{ TeV}, \ A_u = A_d = A_e = 0, \\ 0.3 \text{ TeV} < M_{\tilde{q}_3} < 5 \text{ TeV}, \text{ where, } \tilde{q}_3 \equiv \tilde{t}_L, \tilde{t}_R, \tilde{b}_L, \tilde{b}_R \\ M_{\tilde{q}_1} = 3 \text{ TeV}, \text{ for } i = 1, 2 \text{ and } M_{\tilde{\ell}_1} = 3 \text{ TeV}, \text{ for } i = 1, 2, 3. \end{aligned}$$

- CMS has constrained $\tan \beta M_A$ plane from $H/A \rightarrow \tau^+ \tau^-$ decay.
- ATLAS has constrained $\tan \beta M_{H^{\pm}}$ plane from $H^+ \rightarrow \tau^+ \nu_{\tau}$ in $t\bar{t}$ events, where one $t \rightarrow bH^+$.

[CMS-PAS-HIG-2012-050],[ATLAS Collaboration, JHEP 06 (2012),039]

• 90 < M_A < 250 GeV for tan β > 5.5 is excluded.

• 90 < $M_{H^{\pm}}$ < 150 GeV for 2 < tan β < 6 is excluded.

ILLH in MSSM

- The blue points satisfy following constraints:
 - Lower limits on SUSY particles
 - 95 GeV $< m_h < 101$ GeV; 122 GeV $< m_H < 128$ GeV.
 - $0.1 < \sin^2(\beta \alpha) < 0.25$.
 - $R_{aa}^{H_2}(\gamma\gamma)_{\min} > 0.5$, [CMS : $\hat{\mu} = 0.78^{+0.28}_{-0.26}$].
 - $2.77 \times 10^{-4} < Br(b \to s\gamma) < 4.09 \times 10^{-4}$ at 3σ level. [Br(b → sγ)(exp) = $(3.43 \pm 0.22) \times 10^{-4}$]. [arXiv:1207.1158]. • 0.67 × 10⁻⁹ < Br(B_s → μ⁺μ⁻) < 6.22 × 10⁻⁹ at 2σ level.
- The red circles (enclosing blue points) shows points satisfy the DM relic density constraint (only upper limit): $0.112 < \Omega_{\tilde{v}^0} h^2 < 0.128$.

ILLH in MSSM

- From our previous figure : 130 GeV < M_A <200 GeV for 3 < tan β < 5.5 .
- Direct constraint from $H^{\pm} \rightarrow \tau^+ \nu_{\tau}$ (ATLAS) : blue solid line.
- Exclusion from $H/A \rightarrow \tau^+ \tau^-$: maroon line
- The region of $M_{H^{\pm}}$ < 145 GeV becomes entirely disallowed via $H^+ \rightarrow \tau^+ \nu_{\tau}$ from ATLAS.
- $150 < M_{H^{\pm}} < 200$ GeV.

- Anti-correlation behavior between primary signal strength observables.
- Total Higgs decay width is primarily determined by $h \rightarrow b\bar{b}$ decay width.
- QCD and SUSY QCD corrections to m_b (Δ_b) play important roles in modifying the total decay width/ relevant branching ratios.
- A reduction (enhancement) of $h, H \rightarrow b\bar{b}$ couplings decreases (increases) the total decay width of Higgs.
- Enhances (reduces) the branching ratios to $h, H \rightarrow \gamma \gamma$ increasing (decreasing) $R_{gg}^h(\gamma \gamma)$ or $R_{gg}^H(\gamma \gamma)$.

Mt	MA	tan β	μ	M ₁	M2	M ₃	A _t	Ab

- All masses are in GeV unit
- cross-section is pb unit.
- Main issues of our analysis in MSSM :
- In MSSM one can have 98 GeV and 125 GeV Higgs bosons.
- This restrict : 3 < tan β < 5.5, 130 GeV < M_A < 200 GeV and 150 GeV < $M_{H^{\pm}}$ < 200 GeV

ILLH in NMSSM

- $\lambda \hat{S} \hat{H}_u \hat{H}_d + \frac{\kappa}{3} \hat{S}^3$.
- 3 (2) CP even (odd) neutral Higgses, H_i , i = 1, 2, 3 and A_i , i = 1, 2, and H^{\pm} .
- We vary λ , κ , A_{λ} , A_{κ} , A_0 , m_0 , $m_{1/2}$, tan β , μ_{eff} using NMSSMTools3.2.4.
- In this parameter (figure) space of interest, $M_{A_2} \sim M_{H_3} \sim M_{H^{\pm}}$.
- Heavy mass scale ($M_A > 200 \text{ GeV}$) \implies can accommodate $m_h \sim 98 \text{ GeV}$ (not possible in MSSM with $M_A > 200 \text{ GeV}$.)
- Indirect exclusion: A bit tough, particle masses relatively heavy, so less sensitive at the LHC.
- Exclusion is Model dependent.
- Can we discover/exclude this at LHC in a model independent way ?

Prospect of observing 98 GeV Higgs @ Colliders

- A combination of a 98 GeV & a 125 GeV Higgs boson in the nondecoupling limit of MSSM and in NMSSM.
- Nondecoupling limit of MSSM: → relatively light Higgs bosons → can be probed at the early run of the LHC.
- Non observation of such light Higgs bosons will indirectly exclude the possibility of scenario with a 98 GeV Higgs boson.
- Previous attempts :
- At 8 TeV LHC, 5σ signal for $pp \rightarrow H^{\pm}A^{0}$, $H^{\pm}h^{0} \rightarrow \tau^{\pm}\nu b\bar{b}$ and $pp \rightarrow H^{+}H^{-} \rightarrow \tau^{+}\nu\tau^{-}\bar{\nu}$ can be observed with an integrated luminosity of 7(11) fb⁻¹ and 24(48) fb⁻¹, respectively for $M_{A} = 95(130)$ GeV.
- At the 14 TeV energy : 5σ signal can be observed with an integrated luminosity of 4(7) fb⁻¹ and 10(19) fb⁻¹ respectively. [N.D.Christensen etal. 2012]
- ATLAS search : $130 < M_A < 200$ GeV for tan $\beta \sim 3 5.5$ ruled out the above analysis and some others.

[M. Drees, PRD (2005) & (2012), N.D.Christensen etal. 2012, M. Asano etal. PRD (2012), S. Scopel etal. PRD (2013)].

- Gluon fusion: g g \to H \to $b\bar{b}$ for 98 GeV Higgs boson, large QCD jet background, difficult to prove.
- Di-photon via Gluon fusion: Heavily suppressed BR(H $\rightarrow \gamma \gamma$) for a 98 GeV Higgs, hard to distinguish from the continuous backgrounds.
- VBF production: not so sensitive for a 98 GeV Higgs boson.
- Higgs-strahlung process (VH): H is produced along with a gauge boson W/Z, may have sufficient boost (large p_T of Higgs)

• 2.3 σ excess in the LEP constrains the effective coupling :

 $g_{ZZh}^{BSM}/g_{ZZh}^{SM}\simeq 0.3-0.5$

- \Rightarrow controls the 98 GeV Higgs production cross-section in Vh at LHC
- ⇒ A Model independent input parameter.
- We follow ATLAS simulation considering 20% LEP excess and apply the Jet Substructure technique.
- 80 $< m_{\ell\ell} <$ 100 GeV, [$hZ, Z
 ightarrow e^+ e^- / \mu^+ \mu^-$]

Process	Significance $\left(\frac{S}{\sqrt{B}}\right)$	Combined
ℓνb̄b	1.7	
$\ell^+\ell^-bar{b}$	0.9	2.5
Ę⊤bb	1.6	

- **9** 98 GeV Higgs at the 14 TeV LHC with 300 ${\rm fb}^{-1}$ luminosity is $\sim 2.5\sigma$.
- This signal significance may be reduced further if systematic uncertainties in the SM background estimations are considered.

[ATLAS Collaboration, Report No. ATL-PHYS-PUB-2009-008]

• Associated production of 98 GeV Higgs boson with top quarks:

 $pp
ightarrow t\bar{t}h(h
ightarrow bar{b})$

- $\sigma(pp
 ightarrow t\bar{t}h) \sim$ 1 pb for $m_h \sim$ 100 GeV. at 14 TeV run of LHC. [CERN Yellow Report Page At 14TeV]
- Translated the results already performed by Tilman Plehn et. al. for $\sim 115~GeV$ Standard Model Higgs boson at 14 TeV LHC. [T. Plehn et.al. PRL 104, 111801 (2010)]
- While translating the results of Tilman Plehn for our choice of Higgs mass, we expect enhancements of 60% and 20% in Higgs production rate and background estimation.
- In our analysis, we scale the signal and background by 1.6 and 1.2, respectively for $h(m_h = 98 \text{ GeV}) \rightarrow b\bar{b}$.
- For an integrated luminosity of 300 fb⁻¹ with two tagged b-jets the significance \sim 3.1 σ , while for three b-tag sample \sim 2.6 σ .
- Jet Substructure may marginally exclude the 98 GeV Higgs: experimental collaborations need to perform further detailed analysis.
- In NMSSM A 98 GeV Higgs production from the decay of heavy Higgs bosons as well as from the cascade decays of other sparticles may play an important role at the LHC. [S.F. King et.al. NPB 870,323 (2013); Z.Kang et.al. PRD 88,015006 (2013)]

- There has been a plan to build e^+e^- linear collider (ILC) with \sqrt{s} \sim 250 GeV 1000 GeV.
- Like LEP, the Higgs boson will be produced in $e^+e^- \rightarrow Zh$ channel.
- ILC will be an ideal machine for the Higgs precision study.
- In our analysis, we assume $h \rightarrow b\bar{b}$ decay mode, while Z can decay leptonically or hadronically.
- We use MadGraph5 to estimate the signal as well as SM background cross-section for the 98 GeV Higgs boson.
- For $\sqrt{s} = 250 \text{ GeV}$, $\sigma(e^+e^- \rightarrow Zh) = 350 \text{ fb}$, whereas $\sigma(e^+e^- \rightarrow ZZ) \sim 1.1 \text{ pb}$.
- We find that a 98 GeV Higgs boson can be easily discovered / excluded at the 250 GeV ILC with a 100 $\rm fb^{-1}$ luminosity.
- Discovery potential at the LHC is marginal.
- ILC is an ideal machine to study this scenario.

- We relook the MSSM parameter space in the light of updated Higgs data:
- ATLAS limits :

$$\begin{aligned} R_{\gamma\gamma} &: 1.55^{+0.33}_{-0.28} @ [7 \text{ TeV}(4.8) + 8 \text{ TeV}(20.7)] \\ R_{ZZ^*} &: 1.43^{+0.40}_{-0.35} @ [7 \text{ TeV}(4.6) + 8 \text{ TeV}(20.7)] \\ R_{b\bar{b}} &: 0.2^{+0.7}_{-0.6} @ [7 \text{ TeV}(4.7) + 8 \text{ TeV}(20.3)] \\ R_{\tau^+\tau^-} &: 1.4^{+0.5}_{-0.4} @ [8 \text{ TeV}(20.3)] \end{aligned}$$

• CMS limits :

- $R_{\gamma\gamma}$: 0.78^{+0.28}_{-0.26}@[7 TeV(5.1) + 8 TeV(19.6)]
- R_{ZZ^*} : 0.93^{+0.29}_{-0.25}@[7 TeV(5.1) + 8 TeV(19.7)]

$$R_{b\bar{b}}$$
 : $1.0^{+0.5}_{-0.5}$ @[7 TeV(5.1) + 8 TeV(18.9)]

 $R_{\tau^+\tau^-}$: 0.87^{+0.29}_{-0.29}@[7 TeV(4.9) + 8 TeV(19.7)]

Updated analysis

• All points satisfy following constraints :

- 95 GeV $< m_h <$ 101 GeV and 122 GeV $< m_H <$ 128 GeV
- $0.1 < \sin^2(\beta \alpha) < 0.25$
- $2.77 \times 10^{-4} < Br(b \to s\gamma) < 4.09 \times 10^{-4}$
- $0.67 \times 10^{-9} < \text{Br}(B_s \to \mu^+ \mu^-) < 6.22 \times 10^{-9}$

- All points satisy previous constraints and $R_{\gamma\gamma}$ @2 σ level .
- ATLAS left figure and CMS right figure
- Point to note : 130 GeV < M_A < 200 GeV is allowed from CMS analysis of $H/A \rightarrow \tau^+ \tau^-$.

• Previous constraints plus R_{ZZ^*} and $R_{b\bar{b}}$ @2 σ level

• Previous constraints plus $R_{\tau^+\tau^-}$ @2 σ level .

- We studied the possibility that both the LEP excess in the $b\bar{b}$ final state with a 98 GeV Higgs boson and the LHC signal for a 125 GeV Higgs like object can be simultaneously explained in the most general MSSM framework.
- This can happen in nondecoupling zone of MSSM Higgs sector, where, $M_h \sim M_A \sim M_H \sim M_Z$ or $\sin^2(\beta - \alpha) \rightarrow 0 \implies \cos^2(\beta - \alpha) \rightarrow 1$.
- We have found a region of parameter space in MSSM allowed by heavy flavour physics, CDM constraints, constraints from the XENON100 experiment on the DM direct detection cross-section.
- Both ATLAS & CMS searches on $H/A \rightarrow \tau^+ \tau^-$ and $H^{\pm} \rightarrow \tau^+ \nu_{\tau}$ from ATLAS collaboration severely constraint the parameter space : 130 GeV < M_A < 200 GeV and 150 GeV < $M_{H^{\pm}}$ < 200 GeV.
- For these ranges of M_A and $M_{H^{\pm}}$, tan $\beta \sim 3 5.5$.
- We have shown that at the LHC it will be difficult to probe directly 98 GeV Higgs boson scenario, due low signal significance.

- The most recent data (at 2σ) on Higgs search still allow MSSM parameter space where one can have simultaneously 98 GeV and 125 GeV Higgs boson.
- More precise measurement on Higgs may be able to rule out this scenario indirectly.
- ILC is an ideal machine to explore this possibility.

Thank You!

- Exclude points with over-abundant relic densities, include the possibility of multi-component dark matter.
- Heavy sleptons: no coannihilation with LSPs.
- spin-independent direct detection $\tilde{\chi}_1^0 p$: Region above the solid (black) line discarded via XENON100 data
- Scaled cross-section $(\zeta \sigma_{p\tilde{\chi}_{1}^{0}}^{SI})$: under-abundant relic densities. $\zeta = \min\{1, \Omega_{\tilde{\chi}_{1}^{0}}h^{2}/(\Omega_{CDM}h^{2})_{\min}\}$, where $(\Omega_{CDM}h^{2})_{\min} = 0.112$
- Possibility at future direct-detection experiment XENON-1T

No Boost vs Boost

 $H \rightarrow b\bar{b}$ at rest \implies Two back to back jets

 $m_{H} = 120 \text{ GeV}, p_{T} \gtrsim 200 - 300 \text{ GeV} \Longrightarrow$ large boost $\Longrightarrow \Delta R \approx 2m_{H}/p_{T} \approx 1.2 - 0.8$ $\Delta R = \sqrt{(\Delta \eta)^{2} + (\Delta \phi)^{2}}$

G. Kribs talk @ Fermilab (2011)

Application : $pp \rightarrow VH$, $(V = W^{\pm}, Z)$

- $pp \rightarrow VH$, with $V = W^{\pm}, Z \Longrightarrow$
- $\ell \nu b \overline{b}, \ell \ell b \overline{b}, \nu \overline{\nu} b \overline{b}$ final state
- For Higgs to be boosted $p_T(H) > 200 \text{ GeV}$
- Such a high $p_T(H) \implies \sigma_{\text{boosted}}(WH/ZH) \sim 5\% \text{ of } \sigma_{\text{tot}}(WH/ZH) @$ 14 TeV
- ATLAS simulation @14 TeV with 30fb^{-1} luminosity : $N_S(m_H \sim 120 \text{ GeV}) \sim 13.5$ and $N_B \sim 20.3 \implies \frac{S}{\sqrt{B}} = 3$

Fat jets

- Quantitatively, consider the following thumb rule for a two-body decay: To resolve the two partons of a X \rightarrow q \bar{q} decay,choose a radius (or more generally a jet size) of R < $2M_X/P_T$
- For $P_T \gg M_h R \rightarrow$ very small (Overlap of Jet areas !)
- These highly boosted jets are called "Fat Jets"
- Example: Consider a hadronically decaying W Boson..

• Question : How do I see the inside of this fat jet ?

Jet Substructure

The basis of this technique involves an iterative jet clustering algorithm (e.g C/A), examining subjet kinematics step-by-step, and finally choosing the "best" subjets to form the fat-jet mass.

**Ref: Phys. Rev. Lett. 100.242001, Butterworth, Davison, Rubin & Salam

Step 1: Break the jet j into two subjets(j_1, j_2) by undoing its last stage of clustering s.t $\overline{m_{j_1}} > m_{j_2}$.

Step 2: a) Significant mass drop (MD),

 $m_{j_1} < \mu m_j$

b) Splitting is nearly Symmetric

 $\mathbf{y} = [min(P_{T_{j_1}}^2, P_{T_{j_2}}^2)/m_j^2]\Delta R_{j_1, j_2}^2 > y_{cut}$

• Two parameters μ and y_{cut} are independent of Higgs mass and Higgs p_t .

• $\mu = 0.667$ $y_{cut} = (0.3)^2$

⇒ Helps to reject/minimize QCD contamination.

Step 3: If $y > y_{cut}$, consider j as heavy particle neighborhood and exit the loop.

Otherwise

```
Redefine j to be j_1 and go back to Step 1.
```

In practice, above procedure is not optimal for LHC, when the transverse momentum can be around 250-300 GeV.

Since,

 $m_x \sim 150 \text{ GeV} \implies R_{j_1,j_2} \sim 1.0 \rightarrow \text{Large}$

 \Rightarrow Significant degradation due the Underlying Events (UE)

 \rightarrow UE $\propto R_{j_1,j_2}^4$

Filtering

- To minimize UE contamination ⇒ Filter the subjets j₁, j₂ within a finer angular region, R_{filt} < R_{j1,j2}
- Consider 3 hardest p_T subjets 2b & gluon
- Most Effective result (In the context of Higgs search) \Rightarrow $R_{filt} = min(R_{j_1,j_2}/2, 0.3)$
- (provided, both the subjets have tagged b's)
