- ▶ Large-scale dark matter distribution correlates with that of baryon

IGM-galaxy connection probed by cross-correlation analysis

HI cloud

IGM-galaxy connection

◆ What type of galaxies (M_* , SFR) strongly connect to the IGM?

◆ How is the connection vary among different galaxy populations?

Underdense

Mean density

Overdense

Methodology: cross-correlation analysis

► Cross-correlation between HI transmission excess δ_F and galaxies

$$\xi_{\delta F}(r) = \frac{1}{\sum_{i=1}^{N(r)} \omega_{g,i}} \sum_{i=1}^{N(r)} \omega_{g,i} \delta_{g,i} - \frac{1}{\sum_{j=1}^{M(r)} \omega_{ran,j}} \sum_{j=1}^{M(r)} \omega_{ran,j} \delta_{ran,j}$$

Galaxies

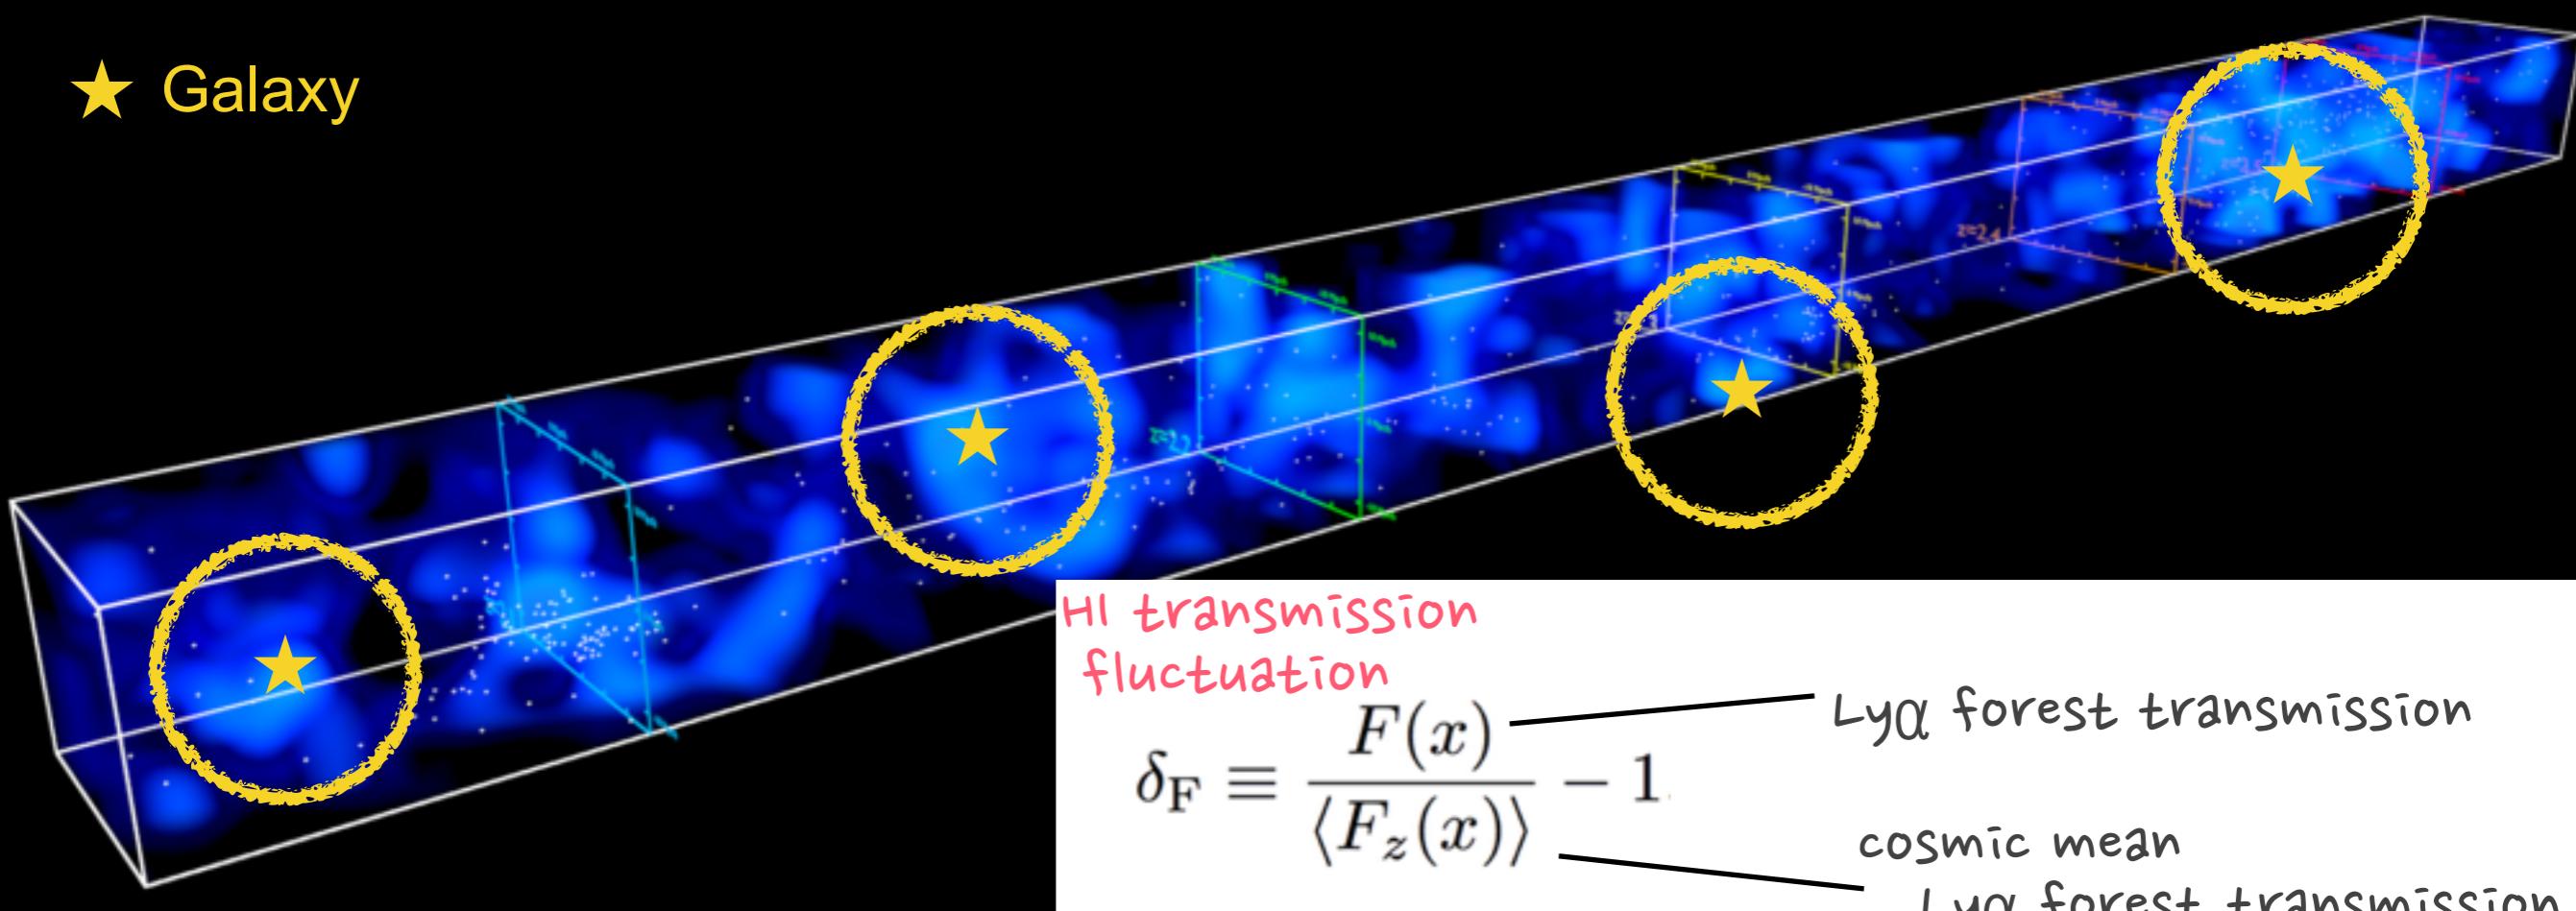

$$\frac{1}{\sum_{j=1}^{M(r)} \omega_{ran,j}} \sum_{j=1}^{M(r)} \omega_{ran,j} \delta_{ran,j}$$

Random points

→ HI transmission excess ($\delta_F = F(z) / F_{cos}(z) - 1$)

- $F(z)$: Ly α forest transmission
- $F_{cos}(z)$: Cosmic mean Ly α forest transmission (Faucher-Giguère+08)

★ Galaxy

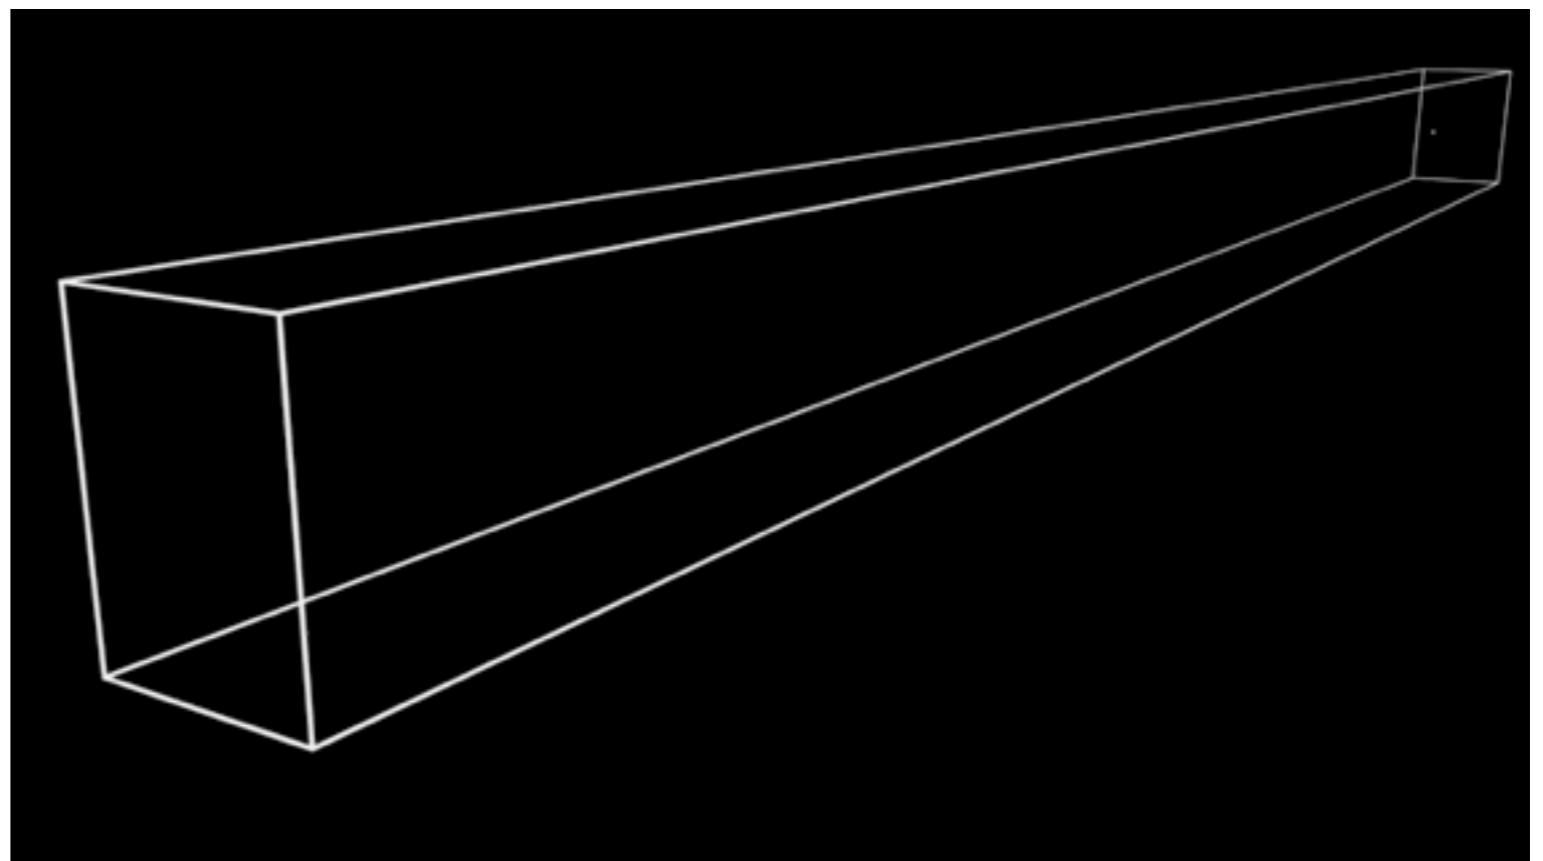

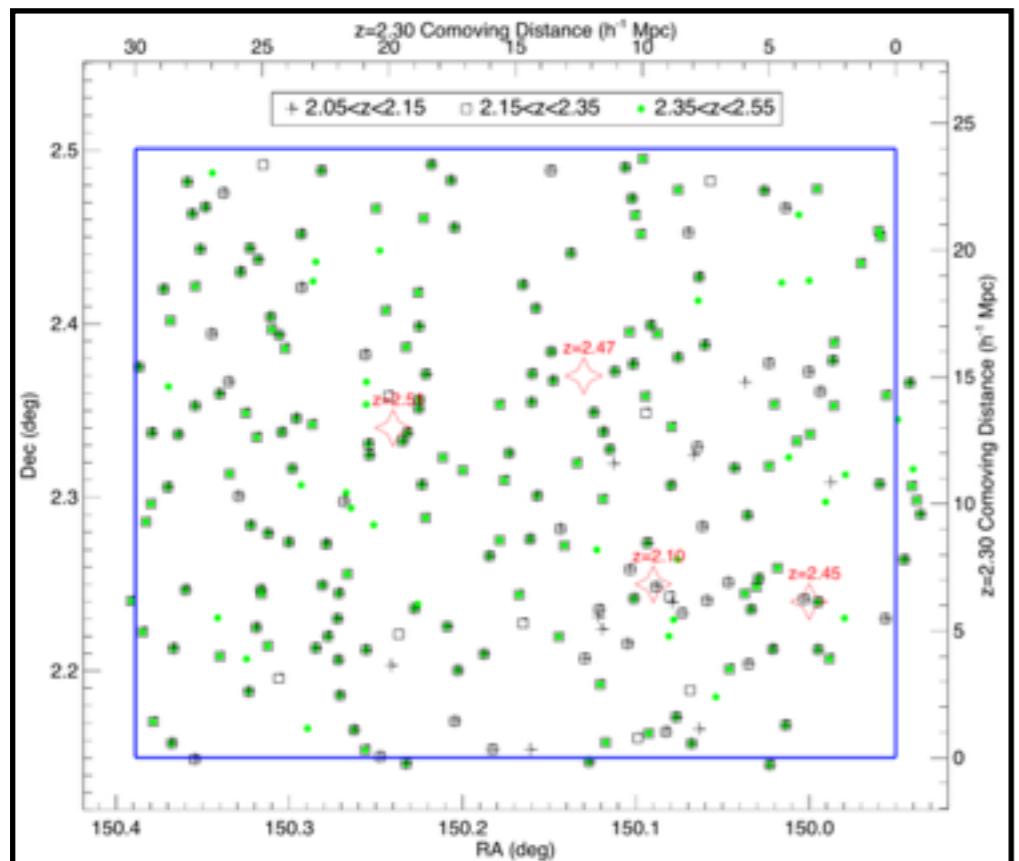

Data

	Observation	Simulation
?	M_* , SFR? Galaxy populations?	M_* , SFR?
IGM	CLAMATO $30 \times 24 \times 438 \text{ (cMpc)}^3$ Lee+18	Light cone from GADGET3-Osaka $100 \times 100 \times 438 \text{ (cMpc)}^3$ at $z \sim 2$ Shimizu+19; Nagamine+ in prep.
Galaxy catalogs	Cont. spec-z (570), LAEs (19), HAEs (7), O3Es (85), AGNs (8, 21), SMGs (4)	90,000 star-forming galaxies with $M_* \geq 10^9 M_\odot$

Observations: CLAMATO

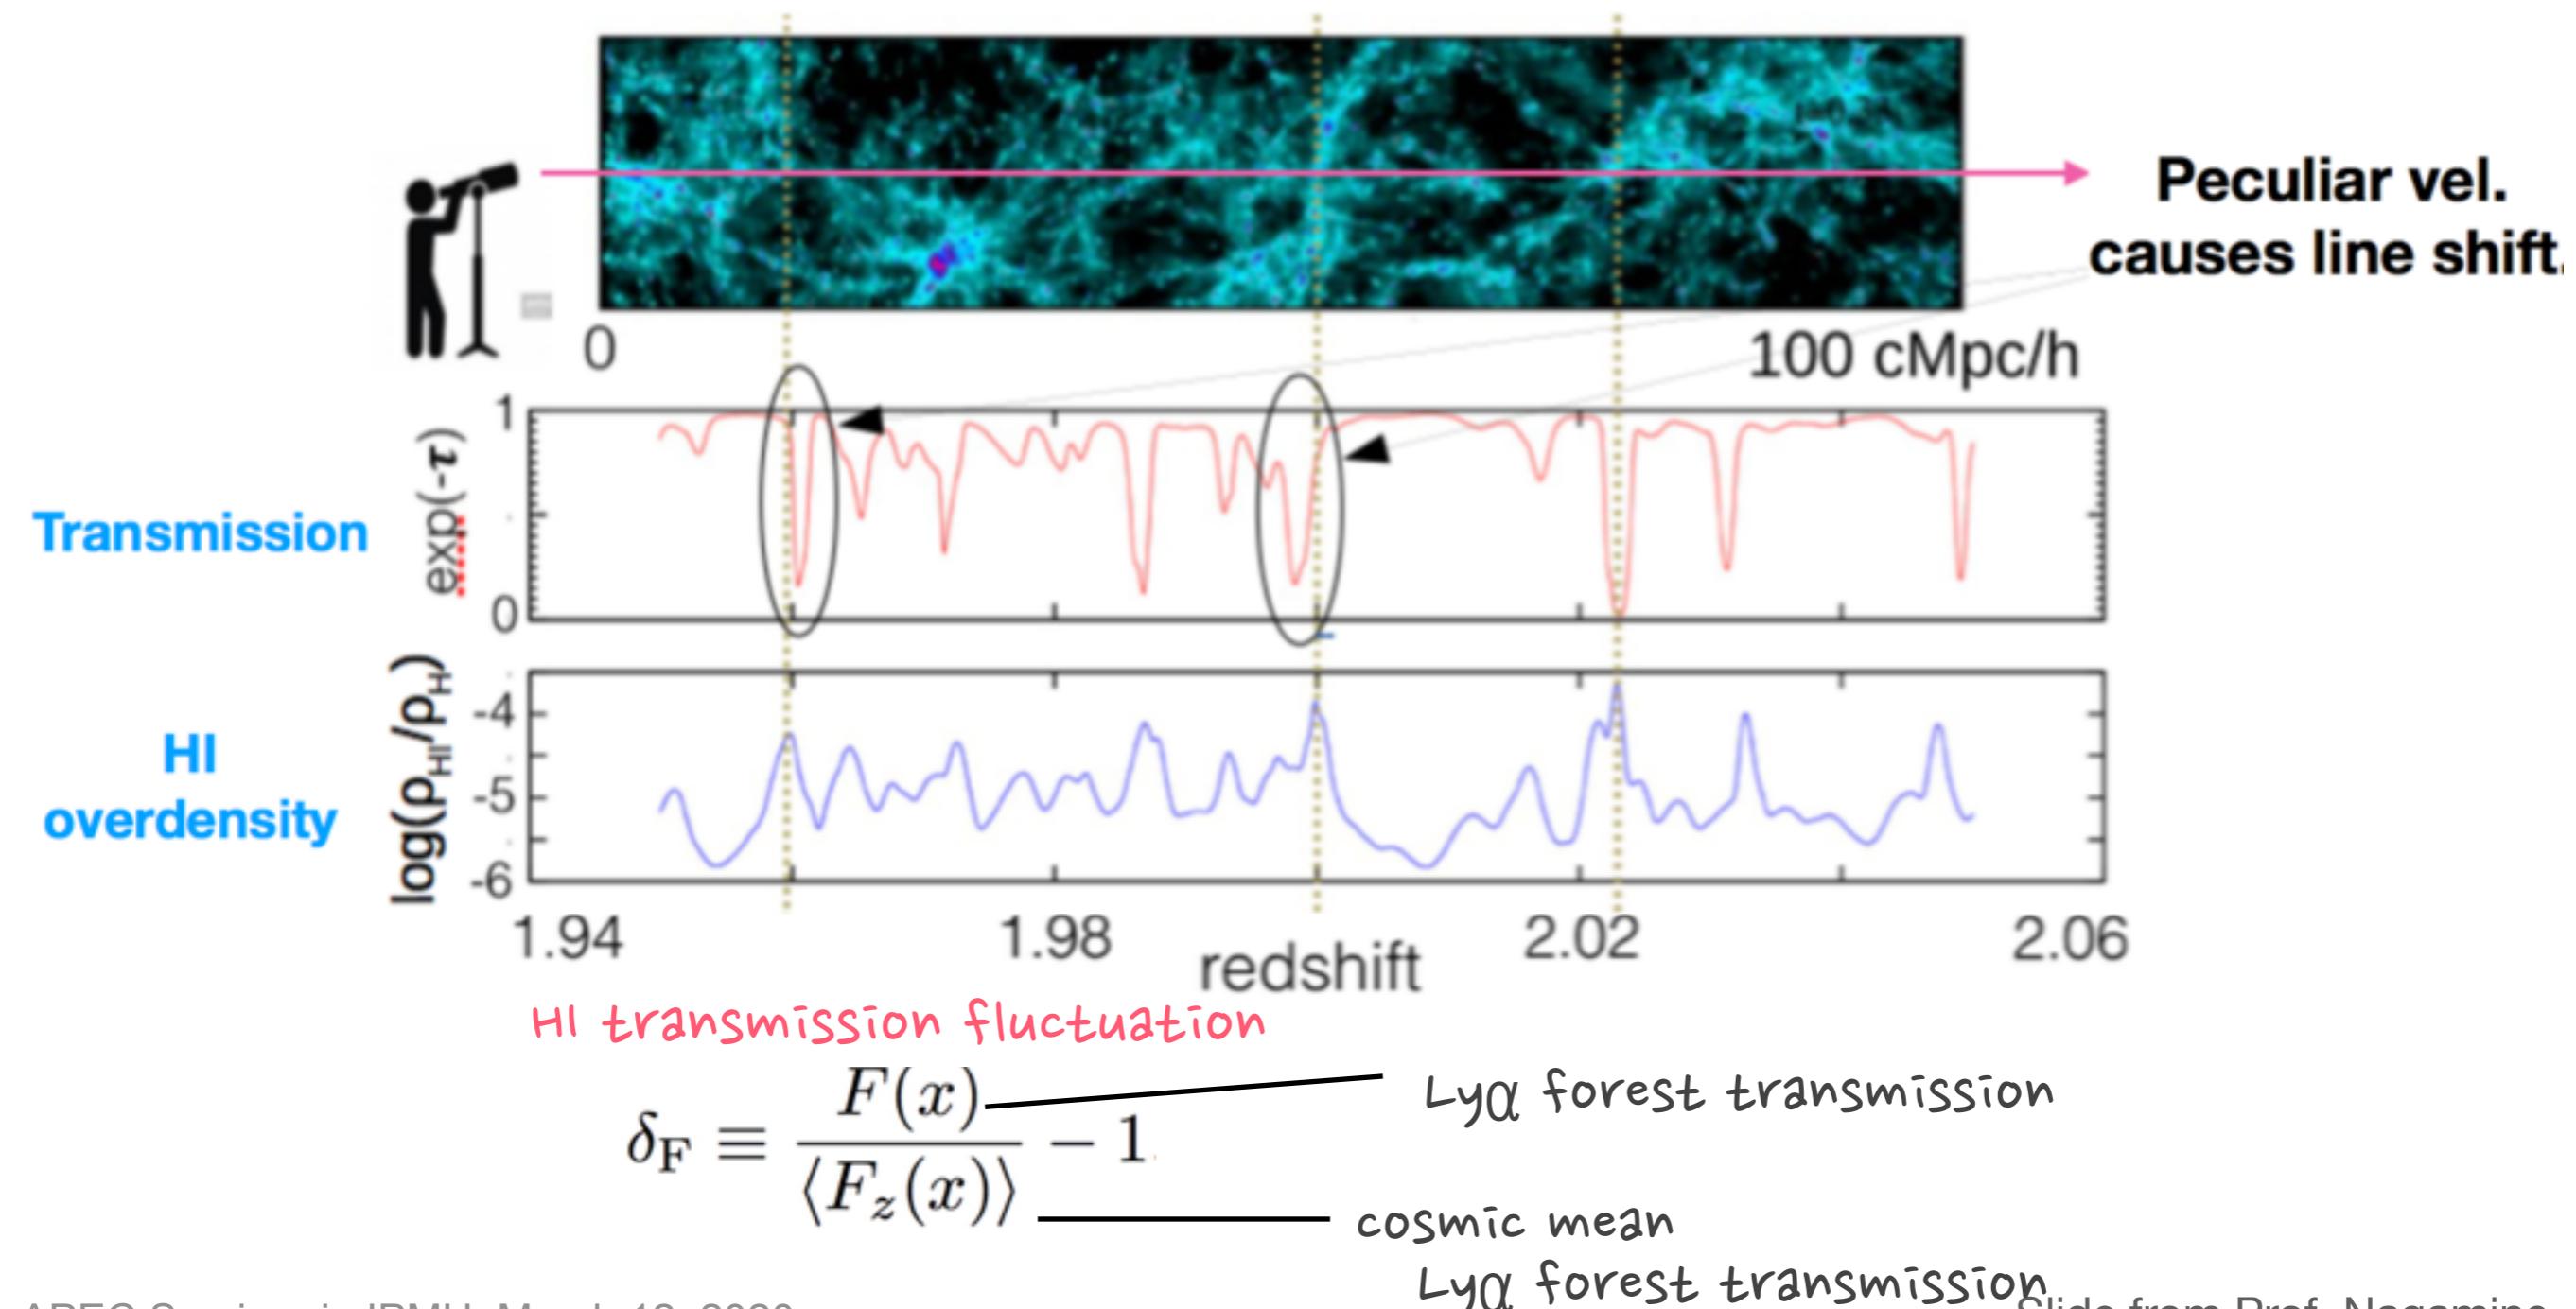

► CLAMATO

- COSMOS Ly α Mapping And Tomography Observations
- Used 240 galaxies and QSOs as background lights
- $30 \times 24 \times 438$ cMpc cube over $2.05 < z < 2.55$

Simulations: GADGET3-Osaka

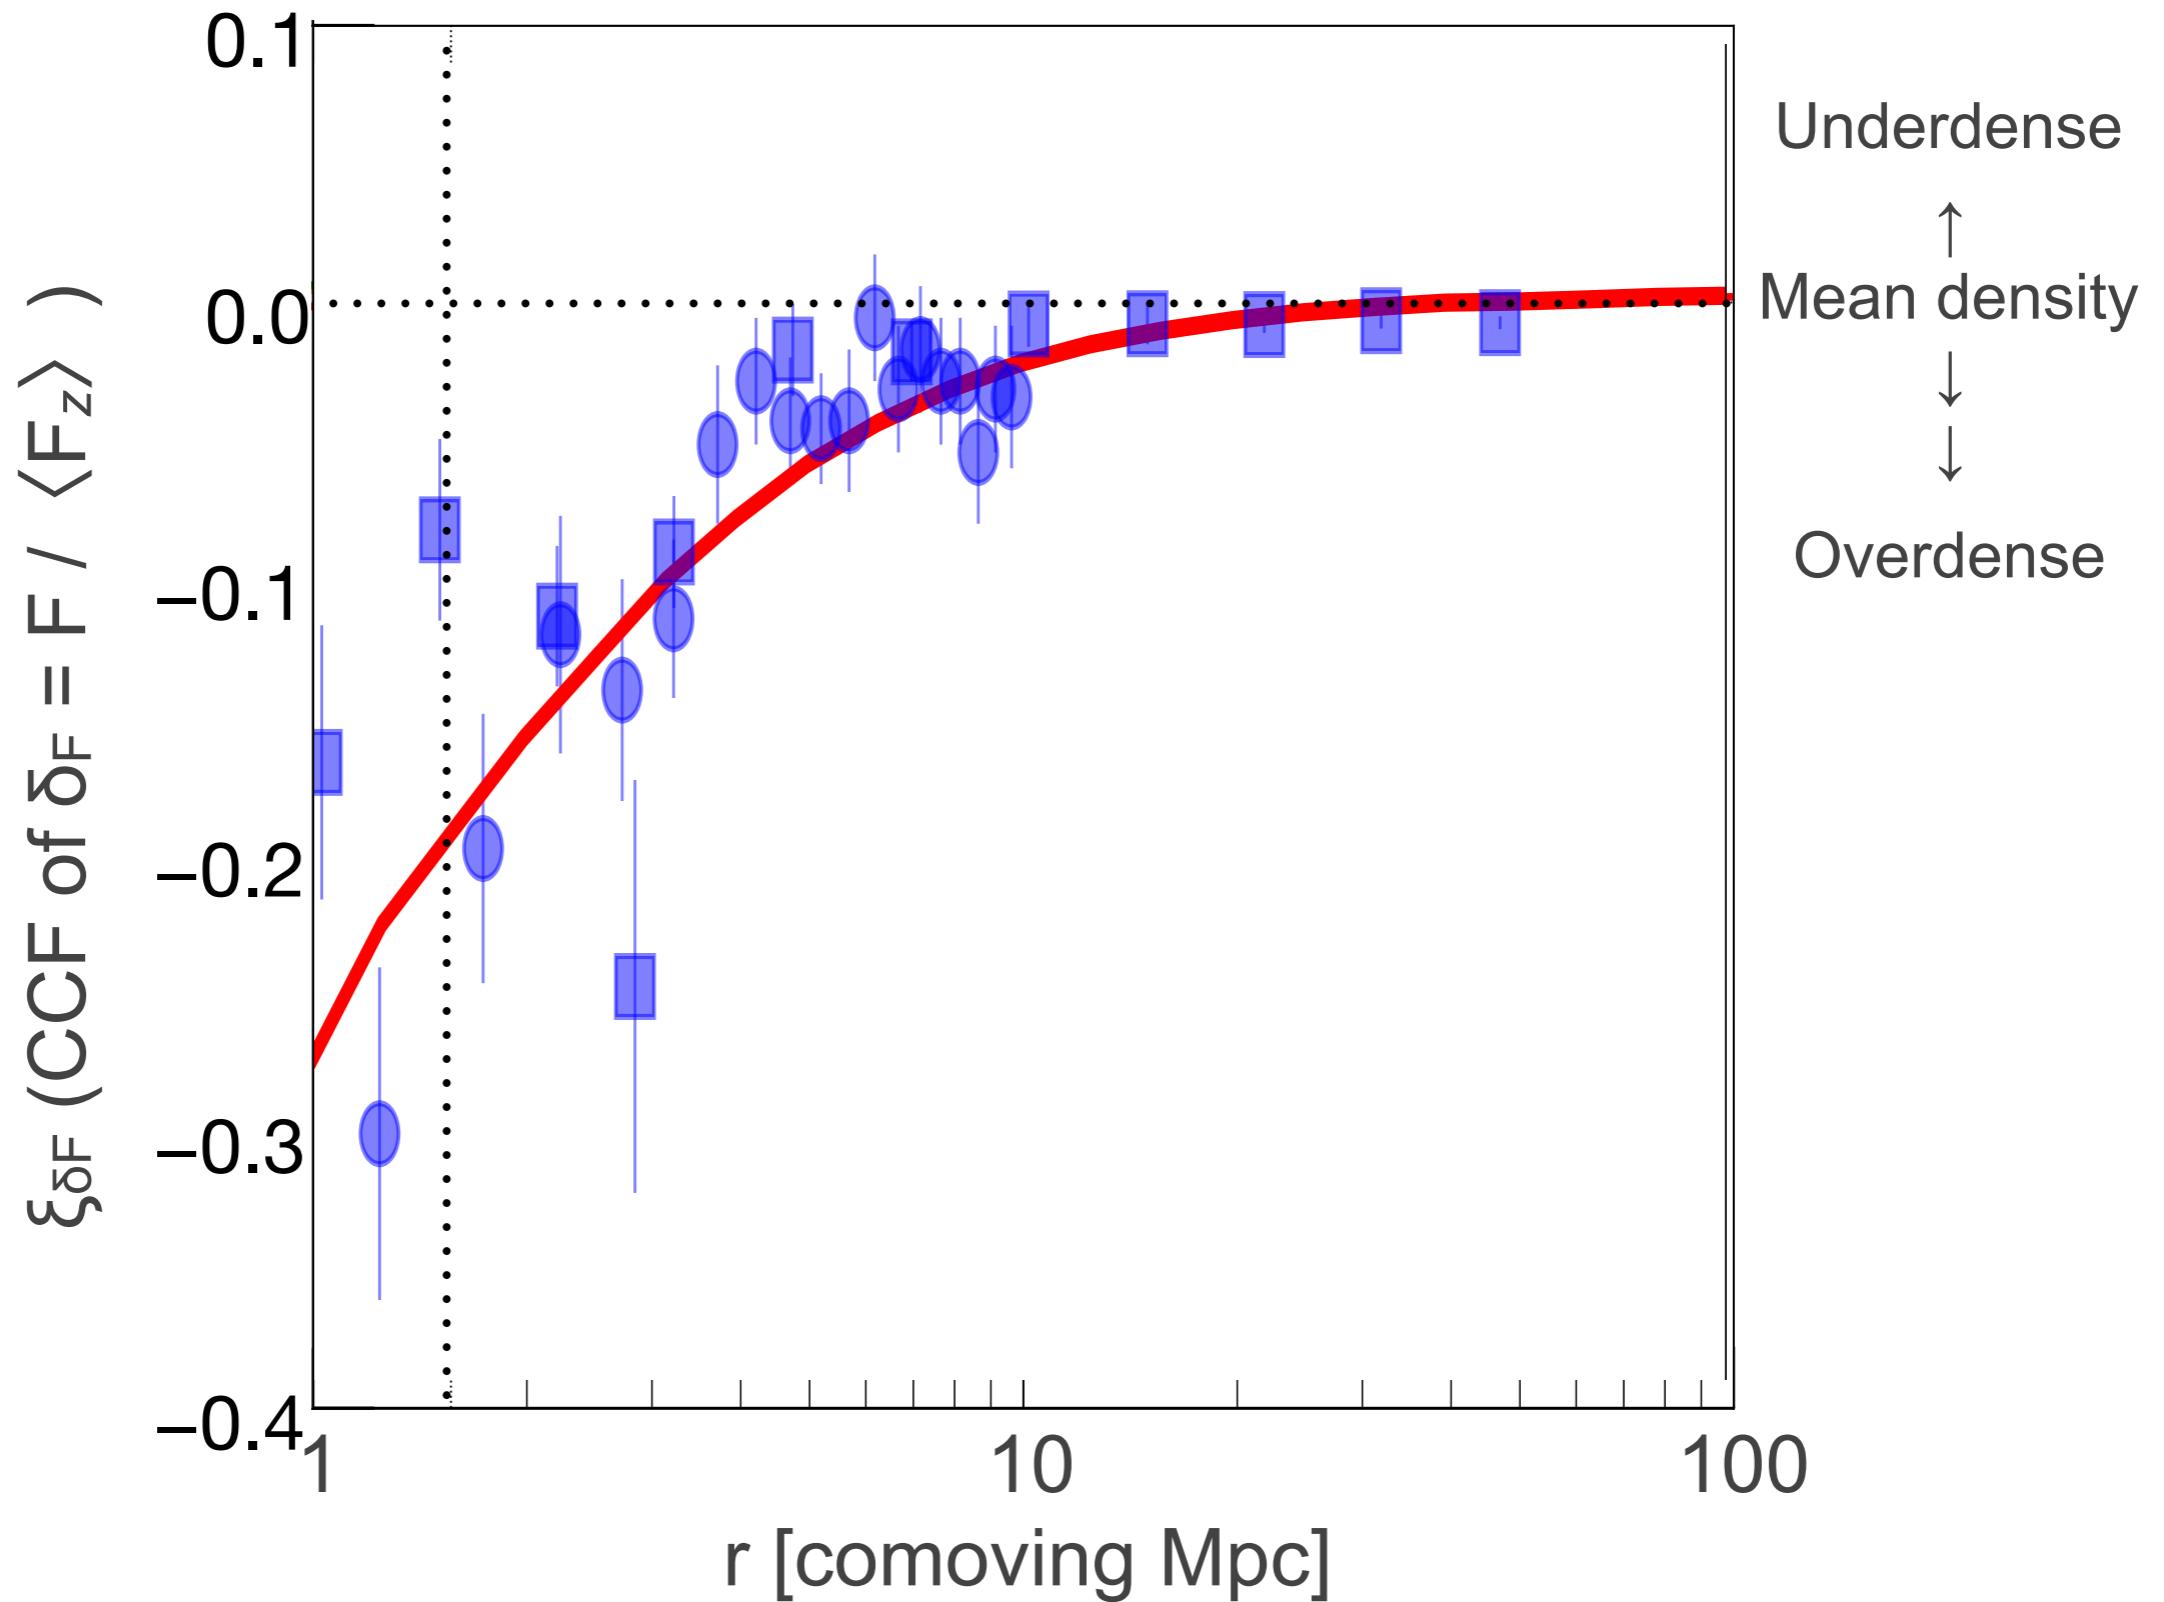

- ▶ GADGET3-Osaka (Shimizu+19, Nagamine+ in prep)
 - $(100 \text{ cMpc})^3$ cubic
 - Produce mock Ly α forest data and measure δ_F at each position

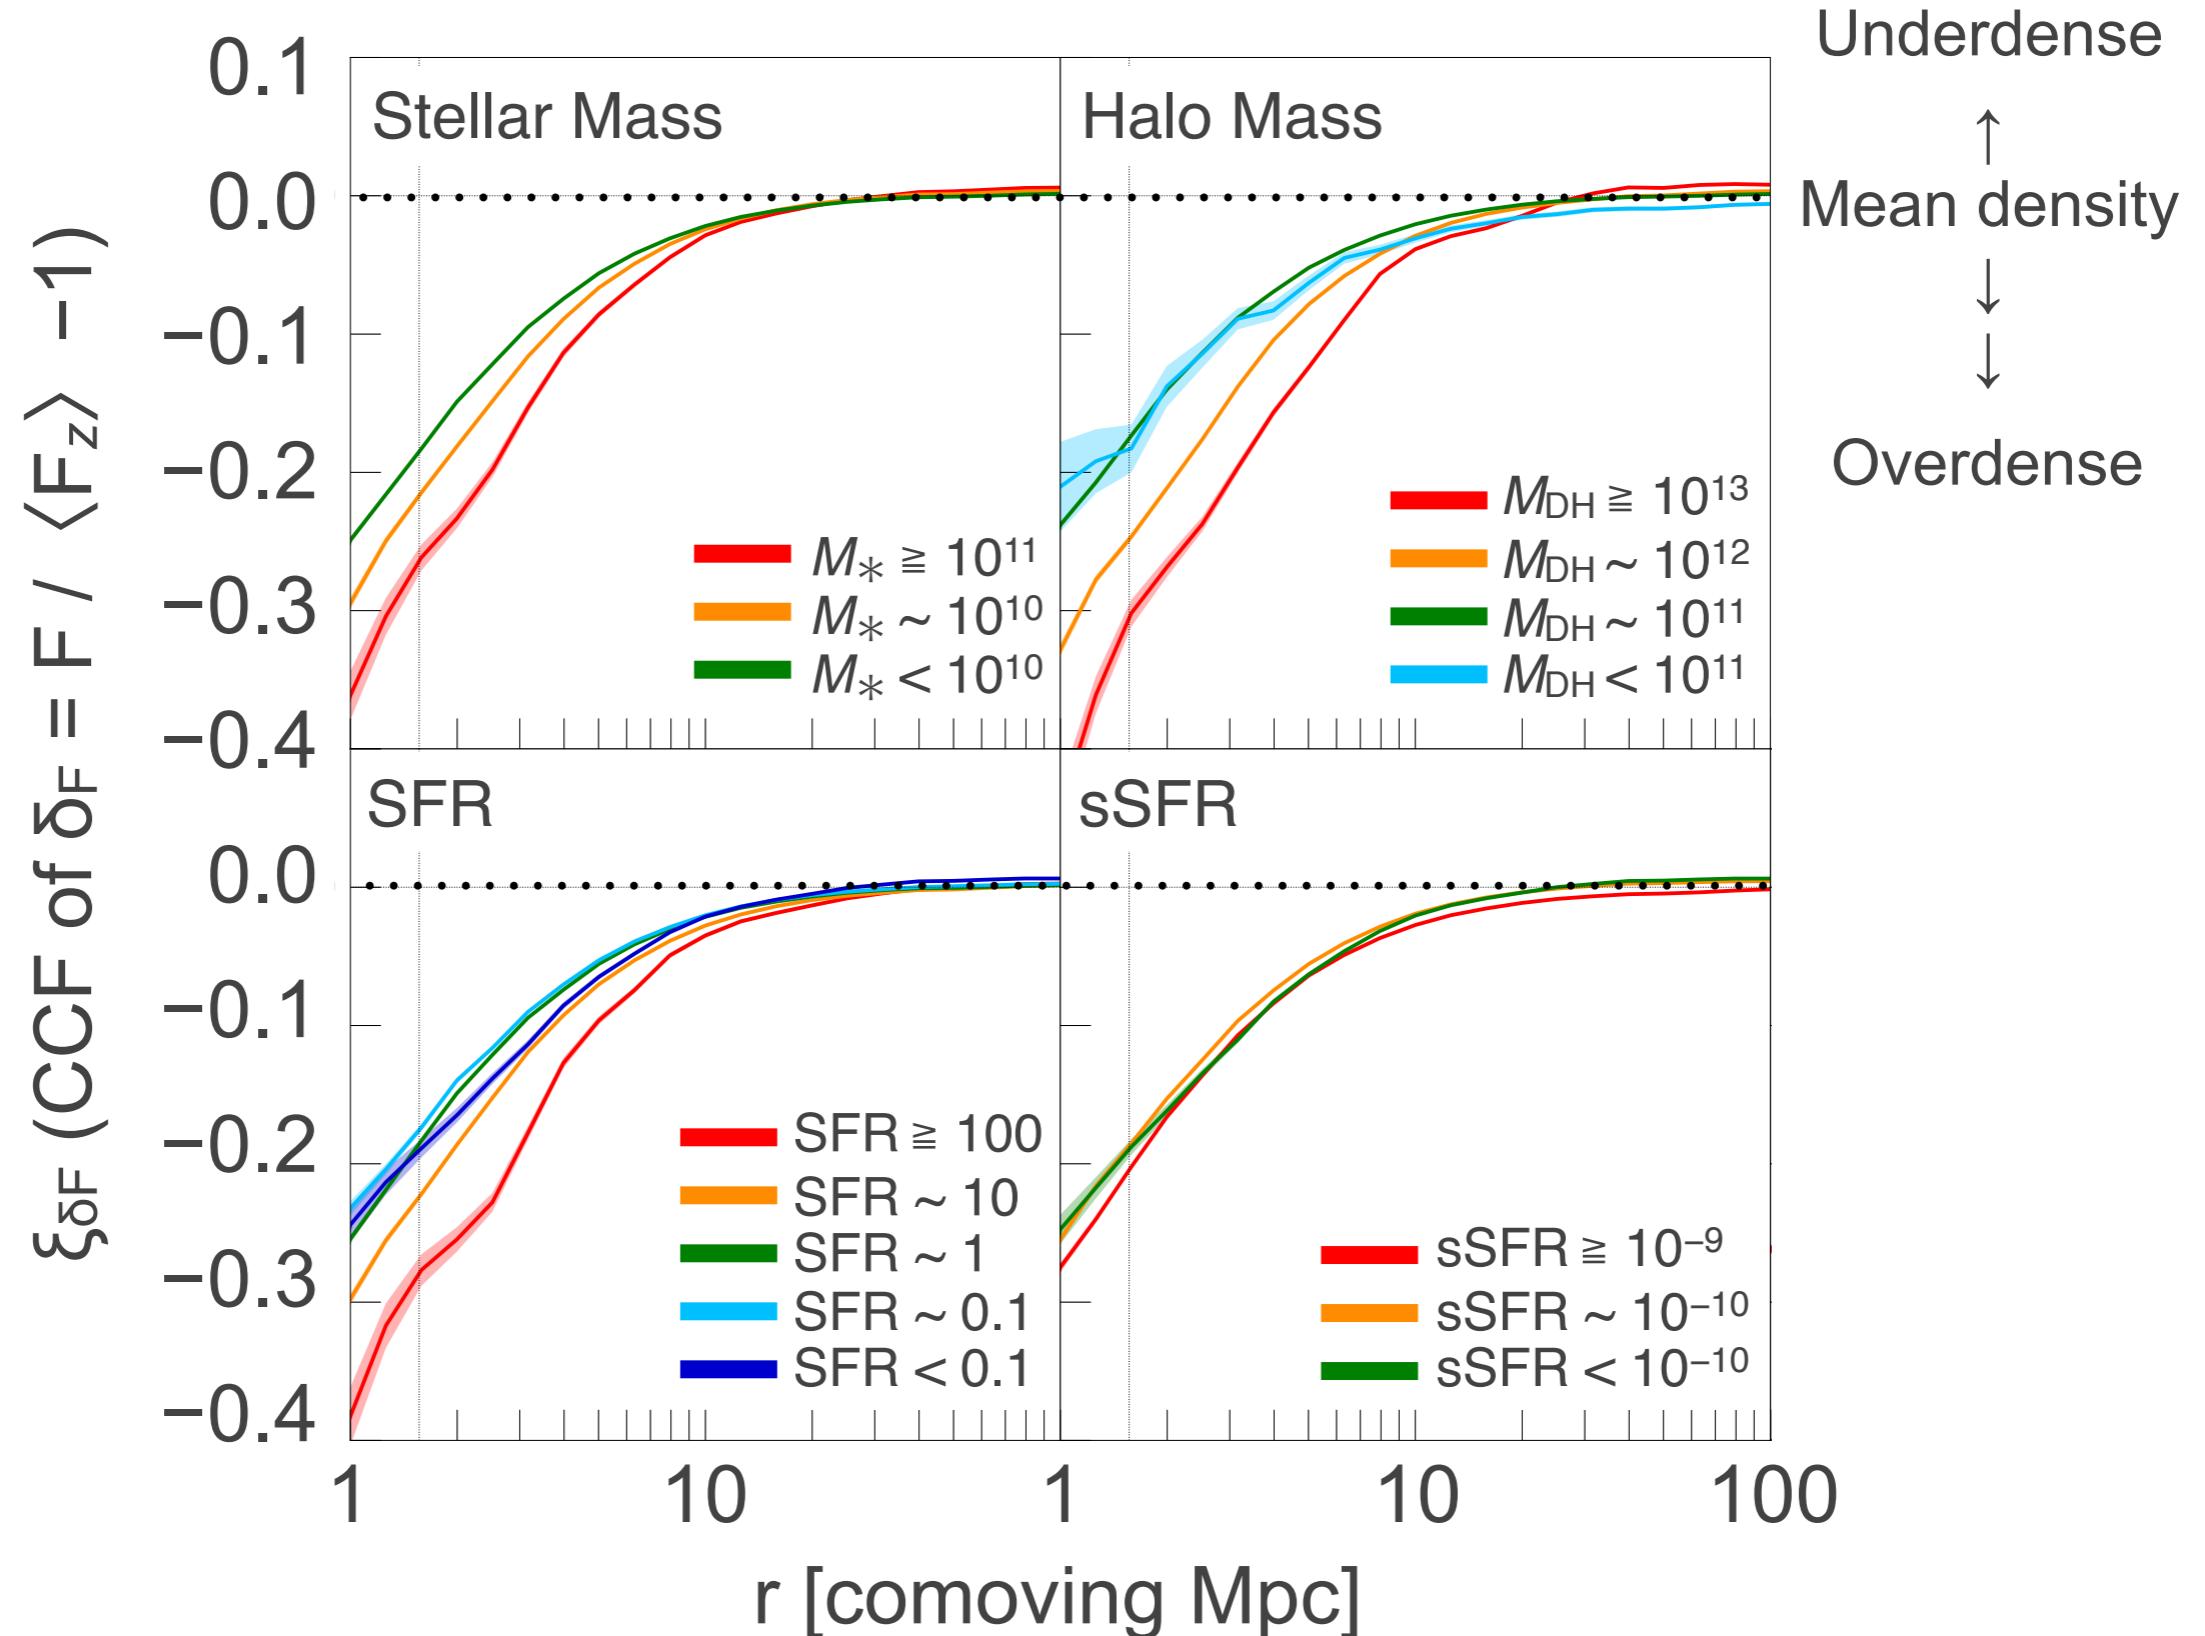

Results & Discussions

The CCF of all galaxies in our simulation

M_* , SFR? CCFs of galaxies depending on their M_* , M_{DH} , SFR and sSFR

Galaxy populations? Preparation for calculations

Continuum selected galaxies with spec-z

Galaxy populations? AGNs and SMGs

A negative bump at $r \sim 5-7$ Mpc/h

Located several Mpc away from a density peak → Proximity effects

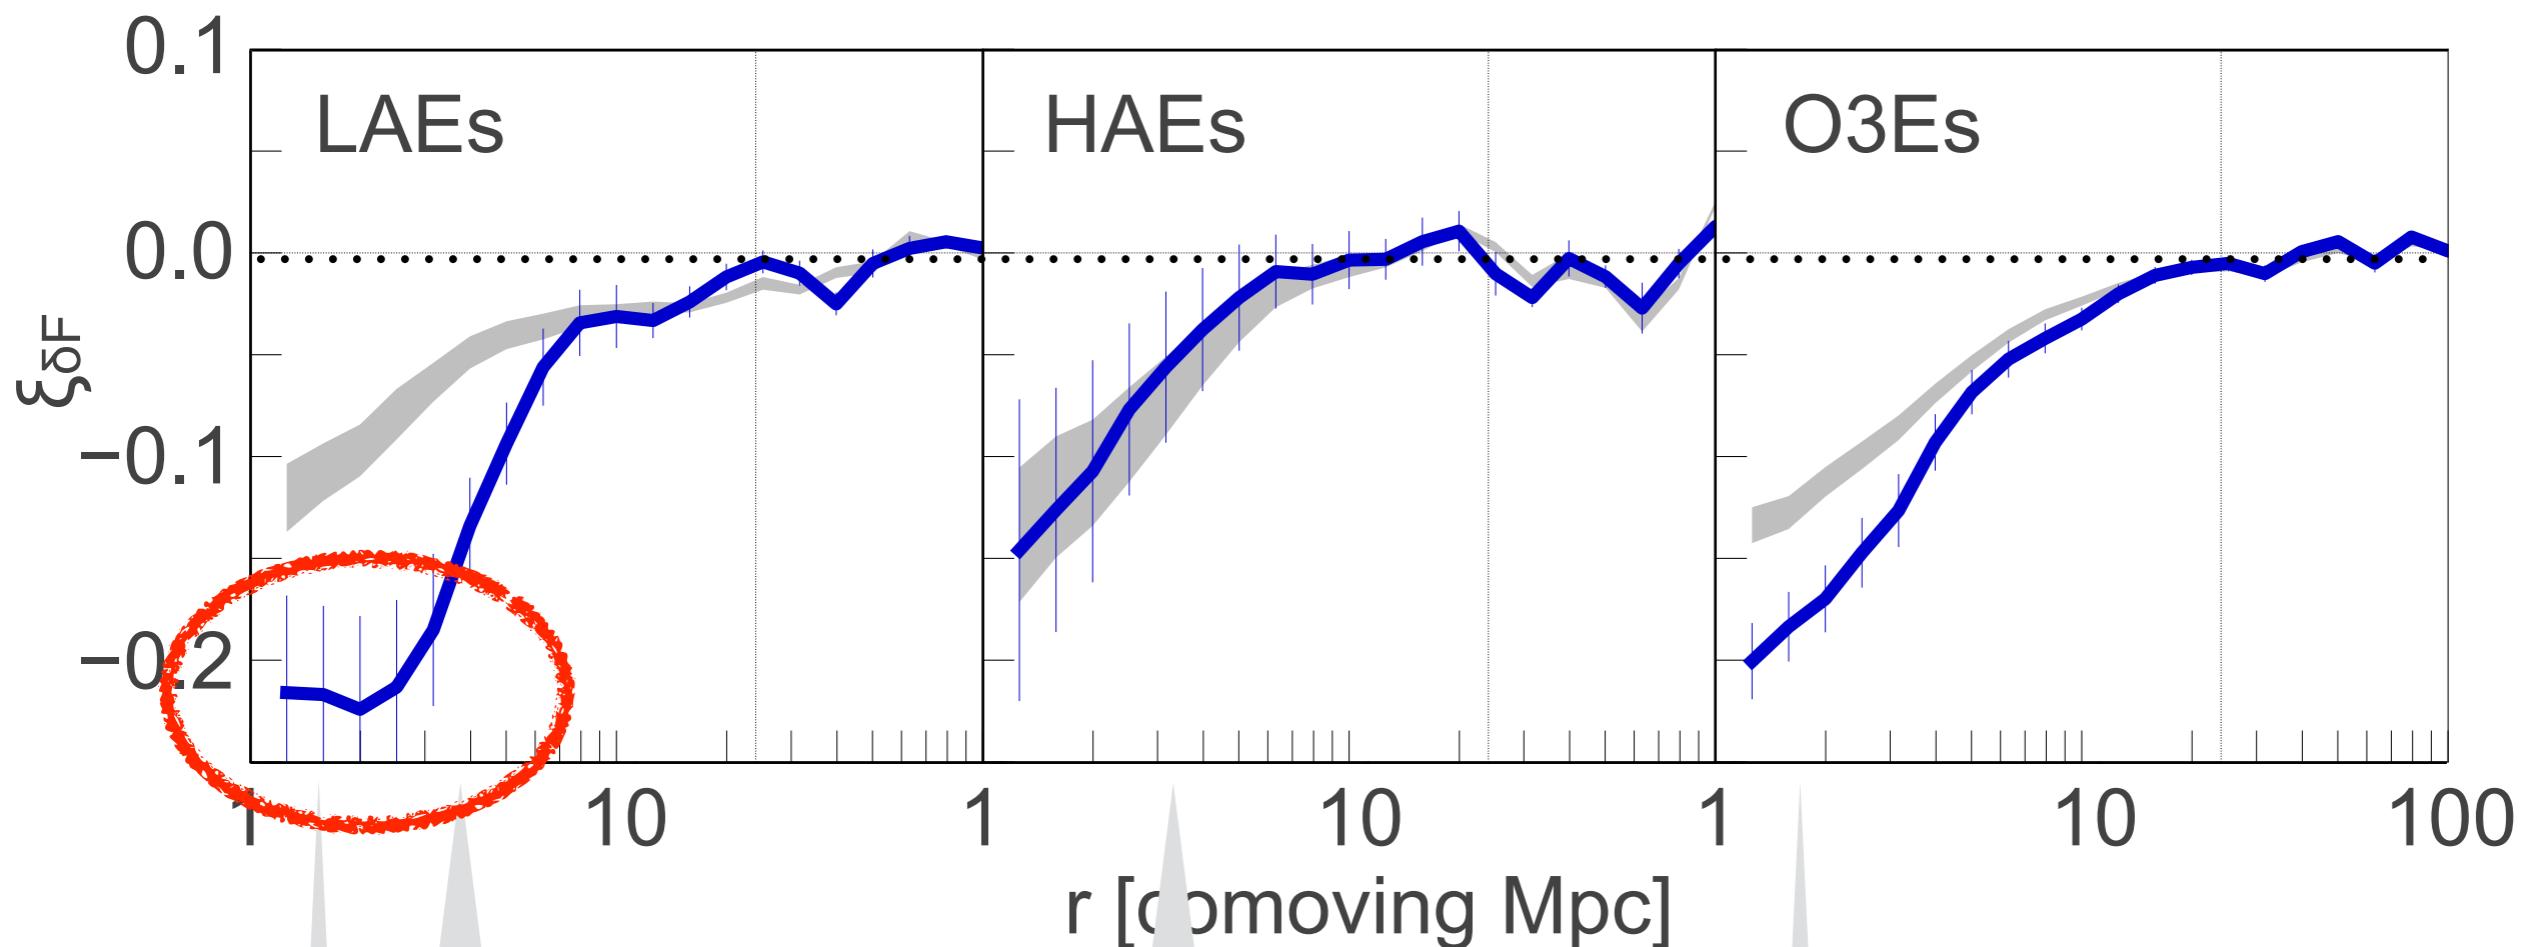

Galaxy populations? AGN types

- ▶ Different CCF trend depending on AGN types
 - IR identified: positive $\xi_{\delta F}$ (underdense)
 - X-ray identified: negative $\xi_{\delta F}$ (overdense)
- ▶ HI gas density of the proximity of AGNs may be determined by the balance
 - IGM photoionization rate
 - Gas accretion rate

Galaxy populations? Line emitters

: Line emitters
: Continuum selected

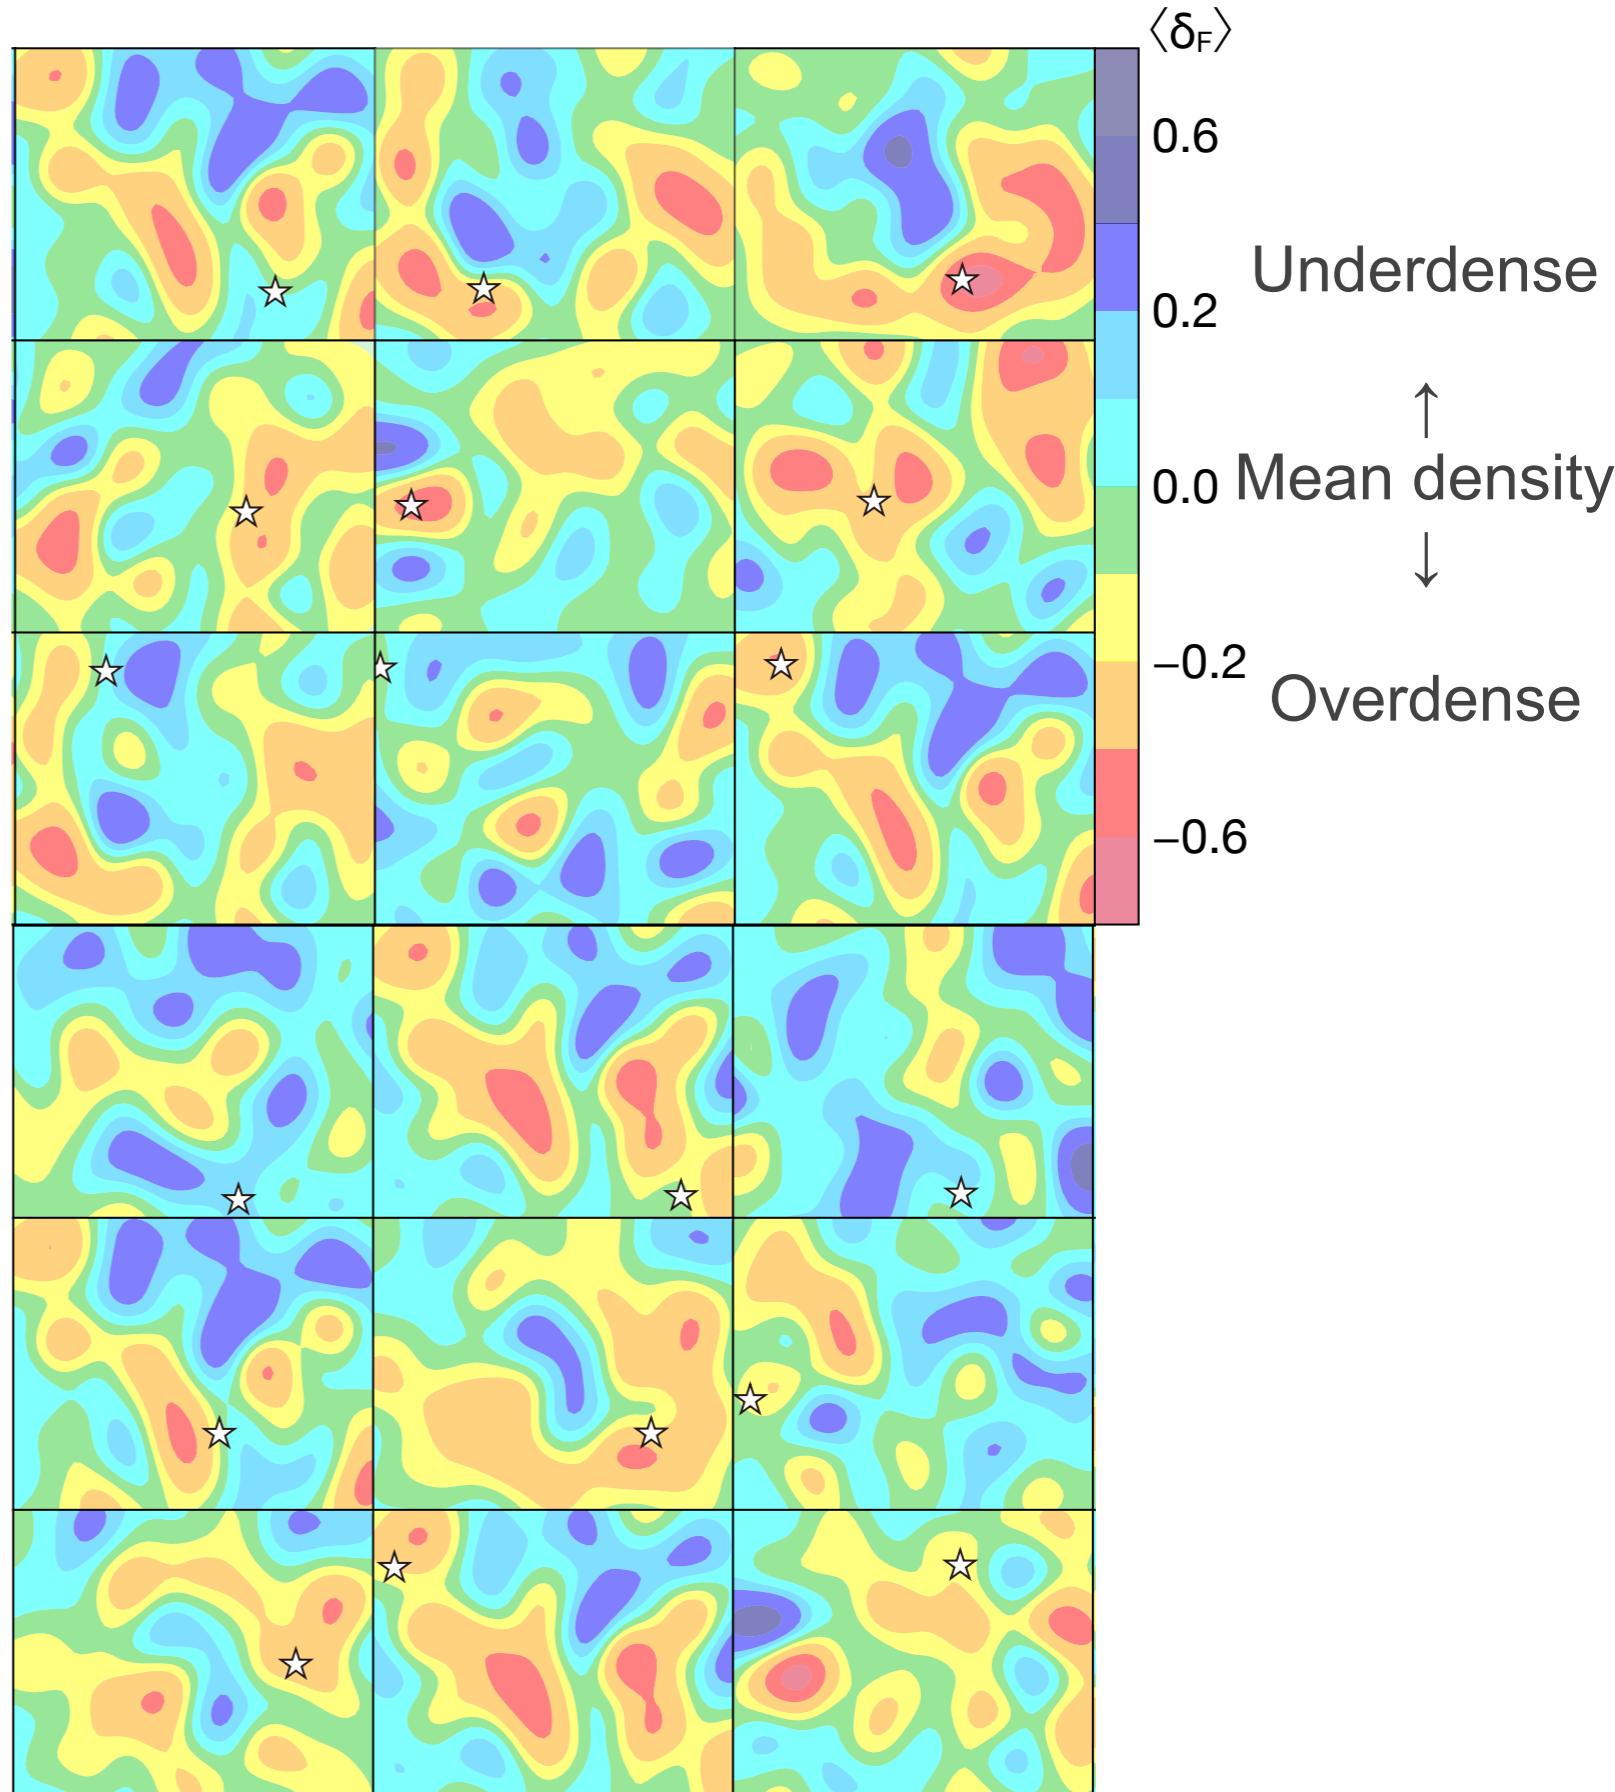

A few Mpc offset
from a density peak

Comparable CCF
→ Similar IGM density

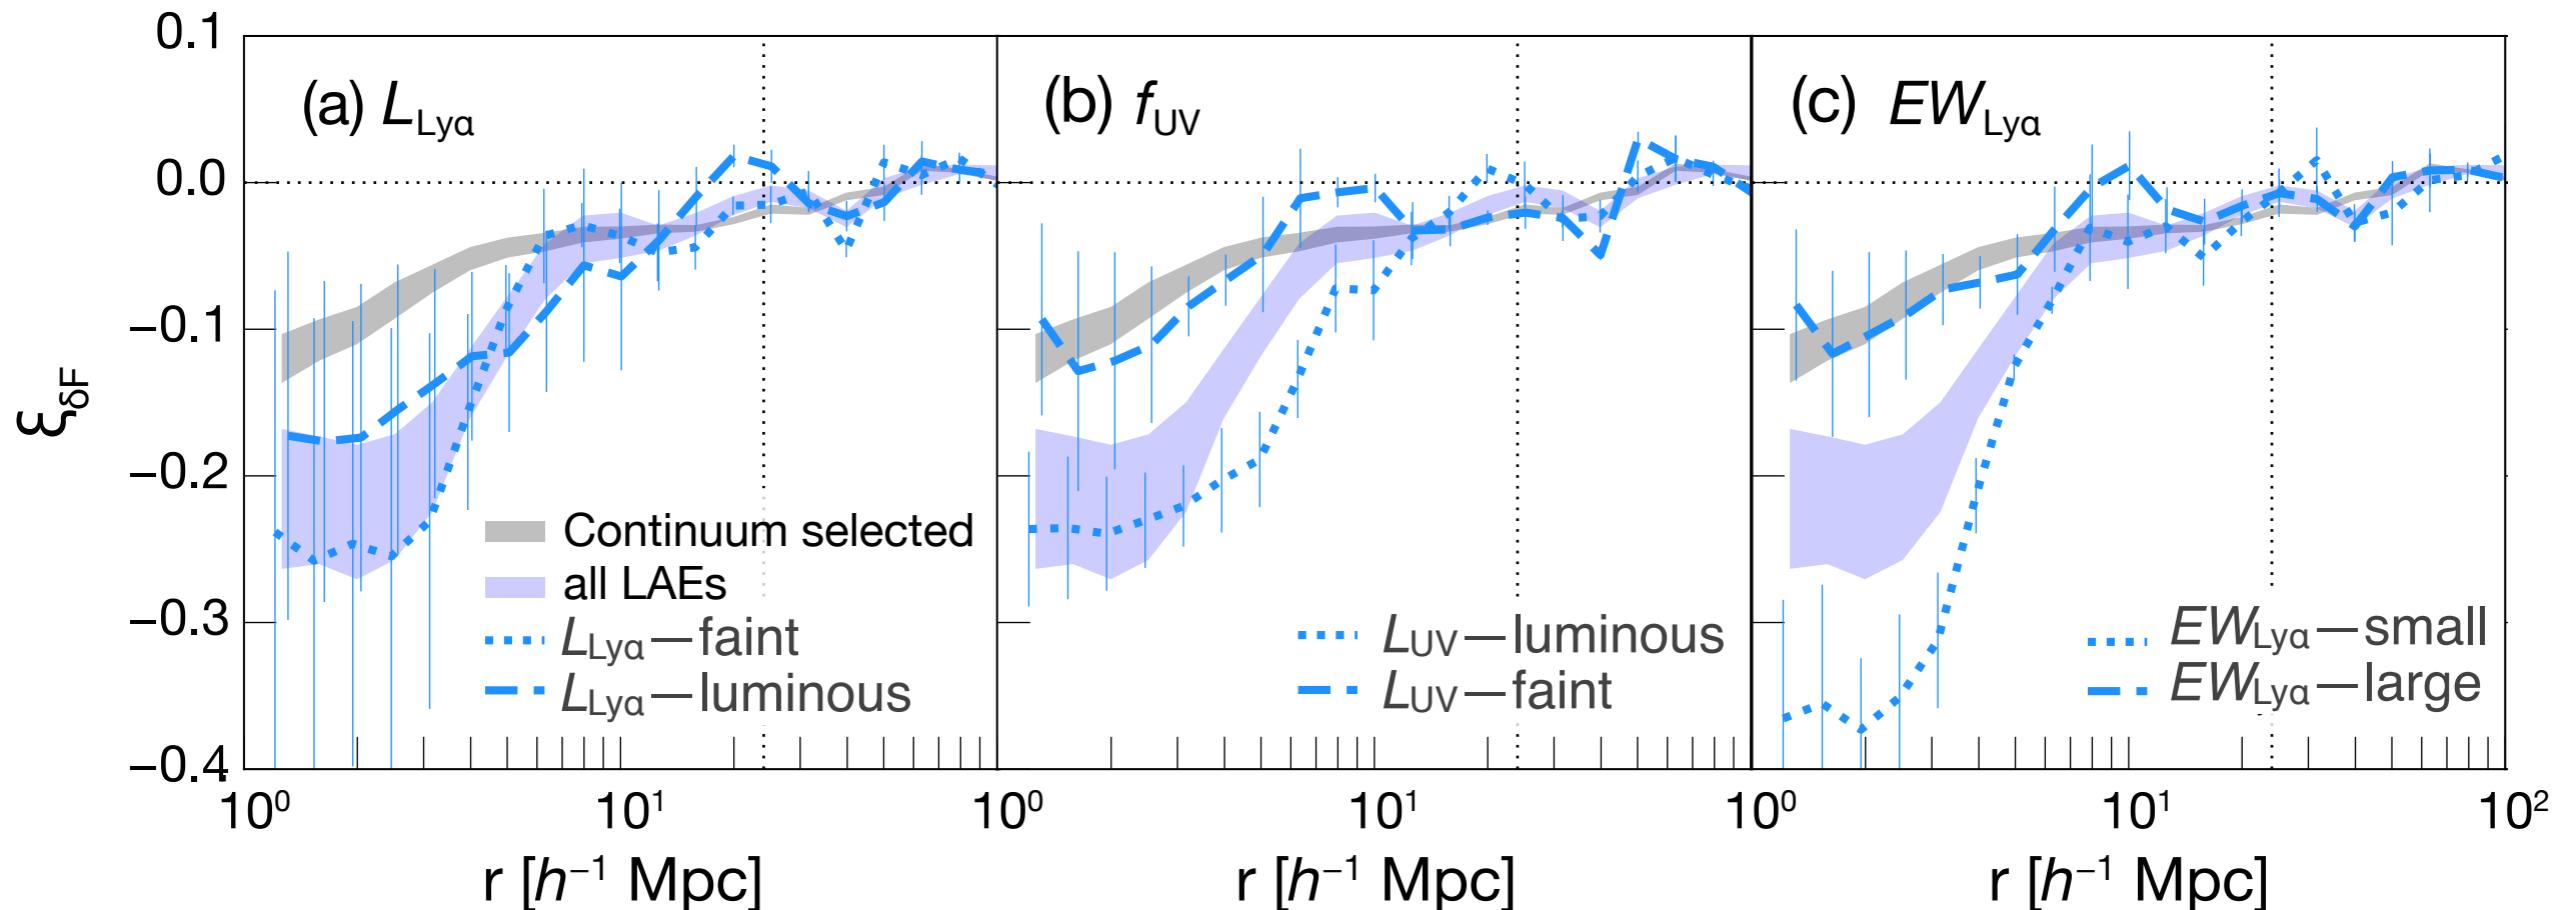

Stronger signal → Denser IGM

Galaxy populations? LAEs

- ▶ Projected HI density maps
 - Collapsing $\Delta z = 2$ cMpc around LAEs
 - Map size: 30×24 cMpc 2
- ▶ LAEs tend to be off-peaks
- ▶ LAEs may not trace the same underlying IGM HI which is traced by other galaxy populations

Galaxy populations? LAEs — further investigations

- ▶ **$L_{\text{Ly}\alpha}$ —faint, L_{UV} —luminous, and $EW_{\text{Ly}\alpha}$ —small** subsamples have **higher CCF signal** than their opposite subsamples
 - They tend to be more massive than the opposite
- ▶ **Massive LAEs can reside in high density regions** than less massive one

Summary: What can we learn about the IGM-galaxy connection?

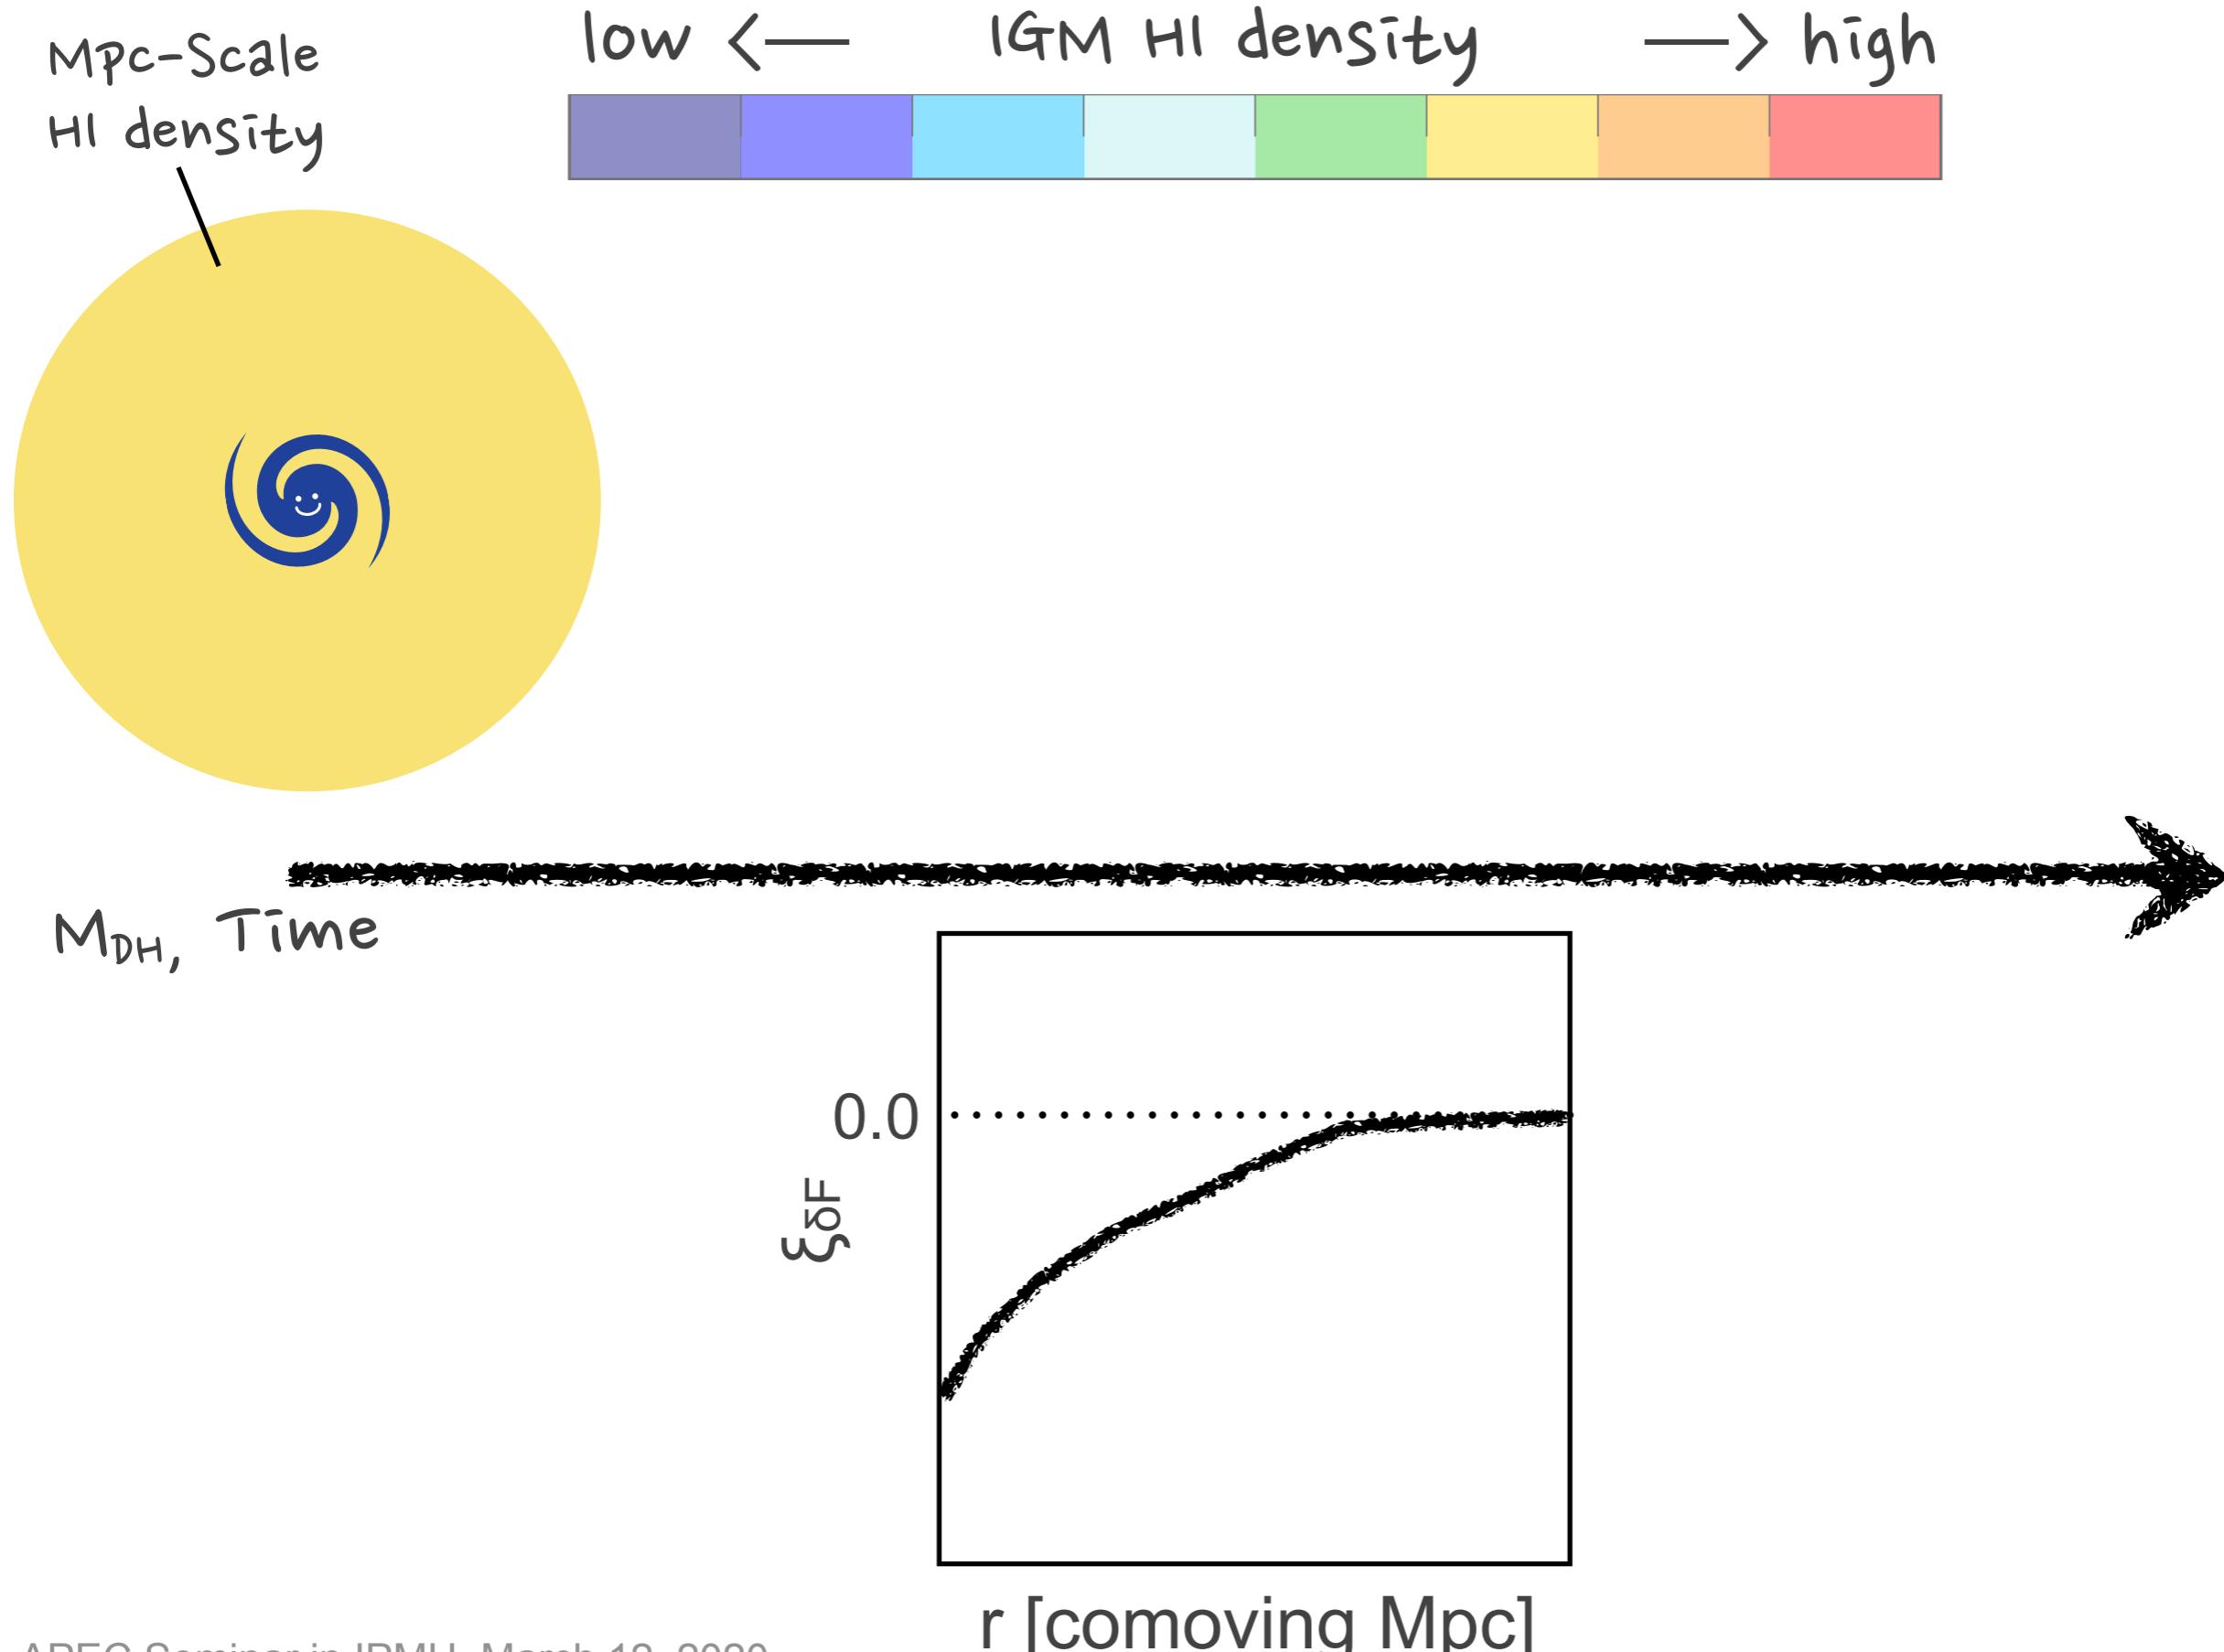

♦ What type of galaxies (M_* , SFR) strongly connect to the IGM?

- Galaxies with higher mass (and SFR) tend to reside in higher density regions

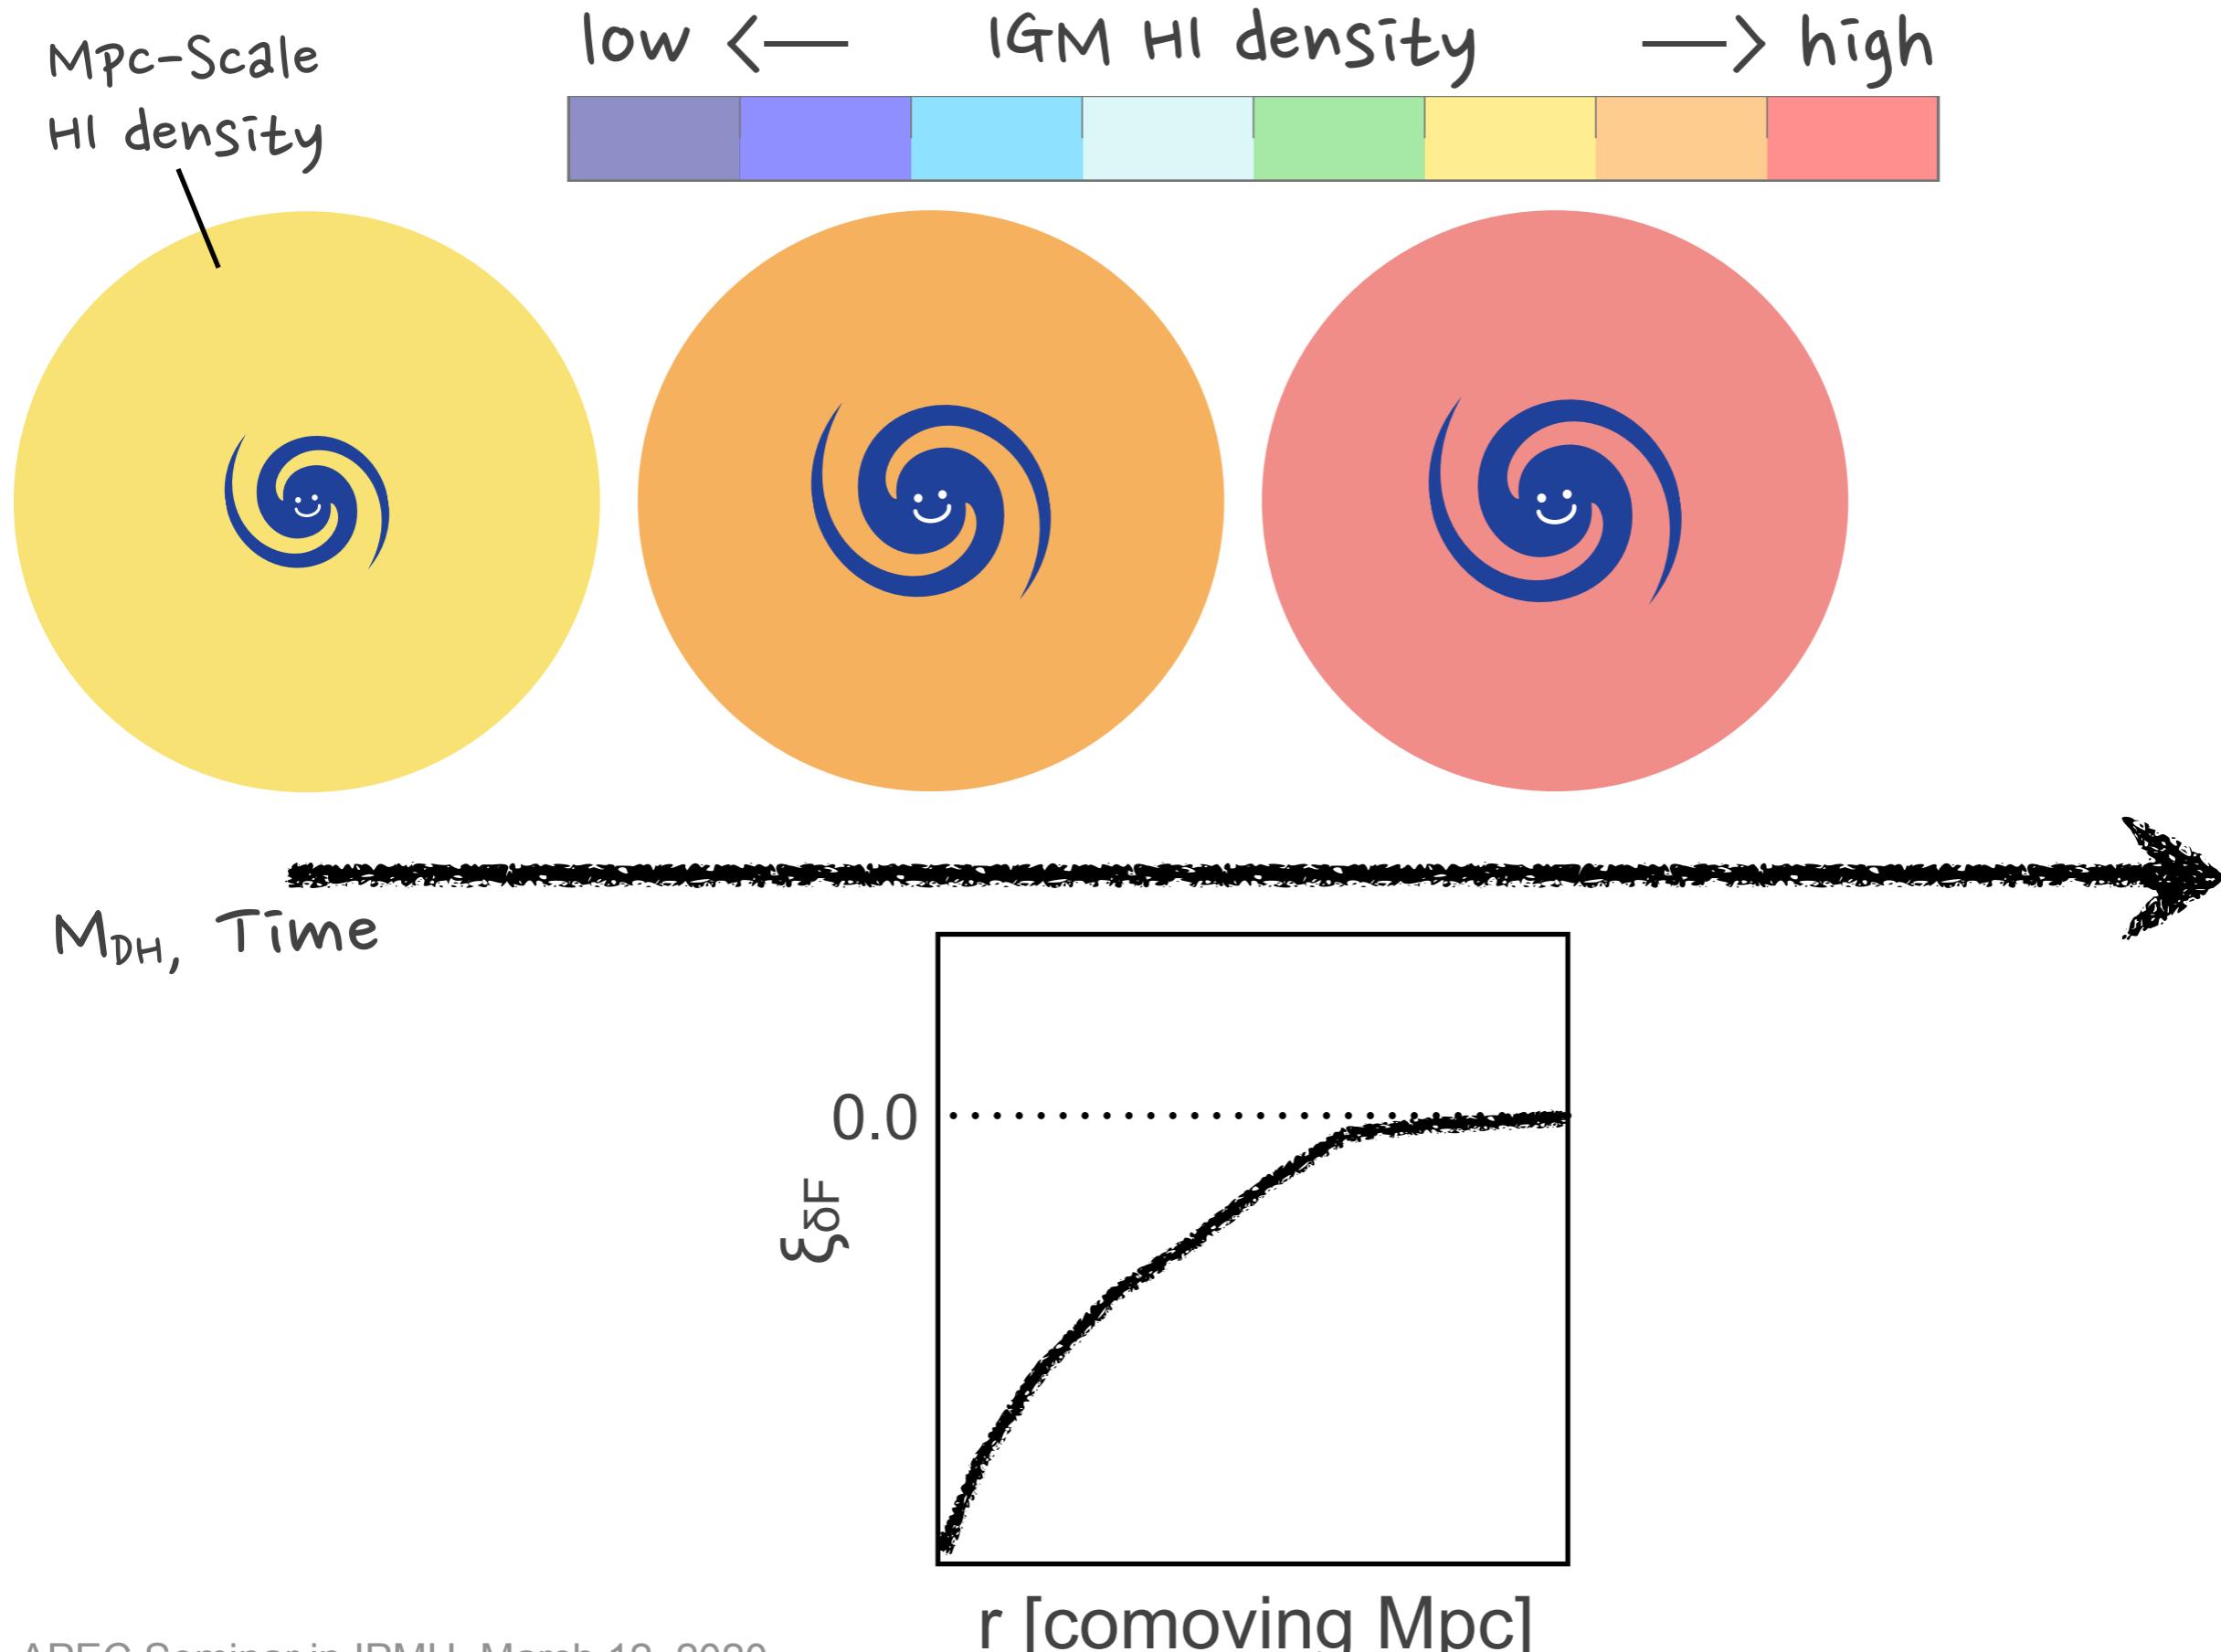

♦ How is the connection different among different galaxy populations?

- AGNs and SMGs are in the highest density regions over $r > 5$ cMpc
 - HI depletion around several cMpc can be due to the proximity effect
- LAEs are in the highest density regions within $r = 5$ cMpc
 - They are not in peaks of the cosmic web, but in a few cMpc off-peaks
- HAEs and O3Es trace the HI density structure well, though O3Es are in higher density
