<u>Plan of Talk</u>

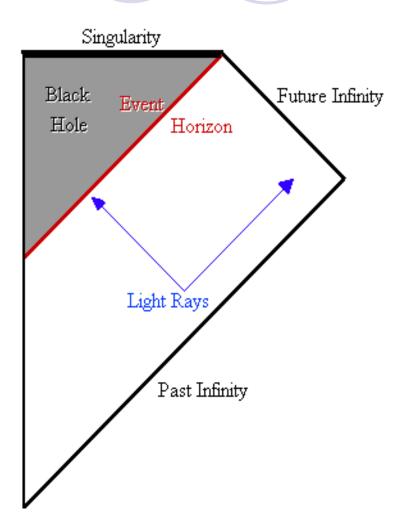

Introduction: Black hole information paradox and motivation

- Toy Model and its SD equation
- Results at zero temperature and non-zero temperature
- Conclusion and discussion
- Further progress: another models with 1/N² corrections

Introduction: Black hole information paradox

Black hole evaporation & information paradox

- Before and after the formation of black hole horizon, the notion of `particles' & `vacuum' changes
- Original `vacuum' is no more vacuum after horizon formation
- It is perfectly thermal state actually black hole radiates as thermal black body radiation

Black hole evaporation & information paradox

- Hawking's argument is quite robust; it works as far as black hole <u>horizon</u> is formed by gravitational collapse
- Since after horizon is formed, the vacuum looks completely thermal, so black hole radiates thermally
- This thermal radiation is parameterized only by the temperature of black hole (surface gravity)
- Therefore, *all the information*, how black hole is formed etc, *are totally lost*, it seems that *pure states evolves into thermal or mixed states*?
- But this contradicts with principles of quantum mechanics (QM): `unitarity'

"Do we have to give up some principle of QM once we include gravity?"

New development of non-pert. quantum gravity

- Discovery of gauge/gravity dual (AdS/CFT)
- AdS/CFT => string theory (as quantum gravity) in <u>asymptotic</u> anti de Sitter (AdS) space = gauge theory without gravity
- There are huge number of evidences showing that this conjecture is correct, and this number keeps increasing!
- This duality says that quantum gravity physics in asymptotic AdS space is equivalent to the physics of some gauge theory with less dimension
- For example, the S-matrix of black hole formation/evaporation must be unitary, since we can map this process by putting it in asymptotic AdS and consider it from dual gauge theory viewpoint, which is always <u>unitary</u>

Now does AdS/CFT solved the problem?

=> In principle yes, but no (yet) in practice.

AdS/CFT should be better understood, since we don't understand

- What is wrong with the original Hawking's argument?
- If information is back, how will it be back?
- How do we see the quasi-local gravity from gauge theory?
- How do we see the non-local effects for black holes from gauge theory?
- How do we see the black hole complementarity?
- etc...

- In this talk, we will concentrate on unitarity issues & information problem
- Hawking's original argument is based on semi-classical approximation. And he showed that black hole radiate thermally, so information is lost.
- This contradicts with gauge/gravity duality, since black hole radiation is dual to unitary gauge theory evolution.
- So how things can be consistent?

Gauge/gravity correspondence

- AdS/CFT correspondence; $G_N \sim 1/N^2$, $l_s^2 R_{AdS} \sim \lambda^{-1/2}$
- Semiclassical approx. is $G_N \to 0$, $l_s^2 R_{AdS} \to 0$ with leading G_N correction only for matter, but not for geometry
- This means, Hawking's argument is at $N \to \infty$ theory in the dual gauge theory (with infinite 't Hooft)
- But note that in N = @, *information* "can" be lost
- This is because in this limit, we have infinite number of states for the system. System can absorb arbitrary amount of information as heat bath
- Also note that the number of states are infinity, Poincare recurrence time also becomes infinity as

(recurrence time scale) ~ $\exp(S) \sim \exp(N^2)$

On the contrary, <u>if N is finite, then the field theory spectrum</u> <u>is discrete (on finite volume)</u>, and it evolves as QM system, <u>so information is never lost</u>

- So the question we would like to understand;
 Can we see the non-unitary black hole physics from unitary (at finite N) gauge theory, by taking N = Ø
- Black hole is characterized by <u>its horizon</u>, where classically all information is incoming, and lost
- BH horizon makes all information (ie, correlation functions) <u>decay exponentially at later time</u> since information is absorbed inside the horizon
- Can we see this exponential decay of correlation functions from unitary gauge theory at $N = \emptyset$?

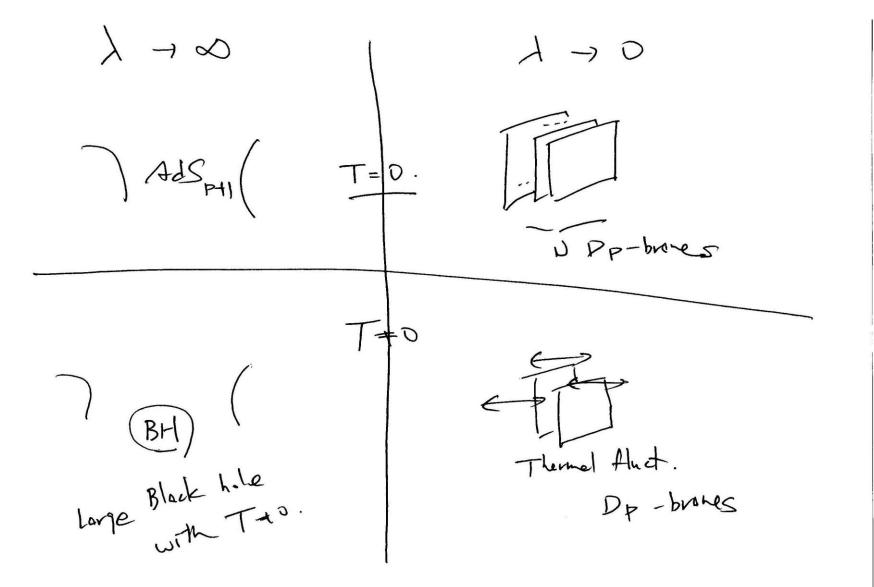

- Our goal is to show this property; the exponential decay of correlation function in N
 Imit, which never occurs at finite N
- Note that exponential decay is not guaranteed, since power law decay is also consistent with information loss.
- The late time decay implies that system is thermalized.
- this late time decay can never been seen by perturbation theory (it is the properties of quantum chaos)
- We simplify the gauge theory system as much as possible, so that we can capture <u>non-pertubative for ●</u>

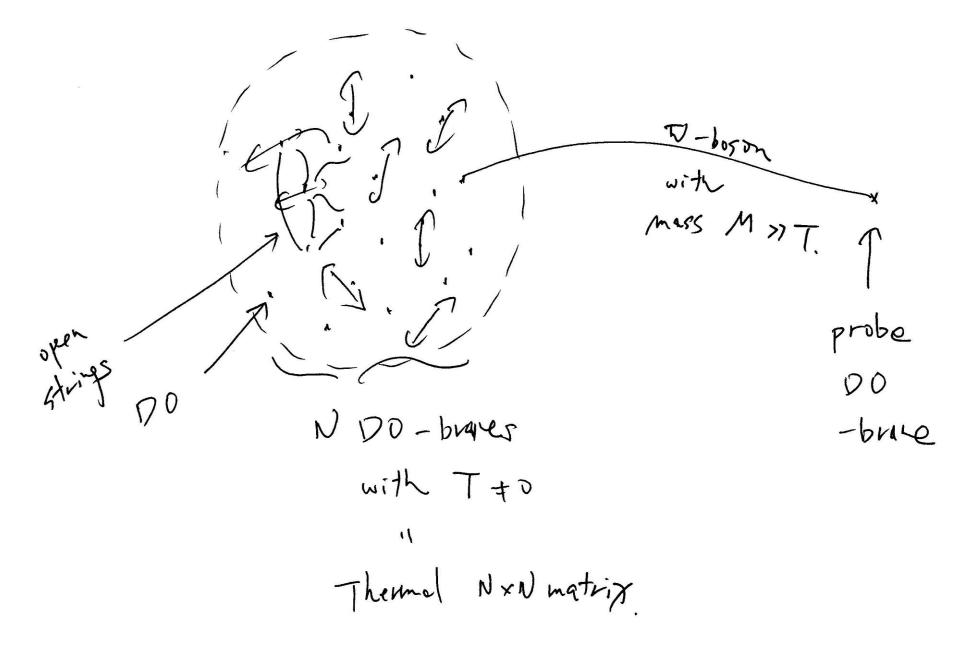

$N = \infty$

• We would like to find simple enough toy model where resumming Feynman diagrams is systematic enough so that we can see the <u>full planner</u> physics <u>non-perturbatively</u>

 $\lambda \neq 0$

- If we can resum all diagrams, unitarity is guaranteed at finite N
- Our toy model is kind of reduction of D0-brane black hole with a probe D0-brane. We have one U(N) adjoint and one U(N) fundamental representation
- Here, [adjoint field] = black hole degrees of freedom and [fundamental field] = open strings or W-bosons between the black hole and a probe
- Adjoint play the role of thermal heat bath, whose correlator are thermal one with some mass m, and since probe is away from black hole, W-bosons masses M are heavy enough
- They couple by Yukawa interaction so that U(N) indices are contracted

- Since fundamental mass M are heavy, they evolves QM way, one the other hand, adjoint mass are light enough they have thermal correlation function
- We actually assign the free thermal correlation function for adjoint field by hand, but we can show that the correlation functions of adjoint field in U = 4 SYM reduces to free thermal one we use in very high enough temperature
- We would like to see how the fundamental fields evolve, through the coupling to adjoint field, and how it can decay exponentially (quasinormal mode) in planer limit which never happen in finite *N*

A Toy Matrix Quantum Mech. Model

0

$$H = \frac{1}{2} \text{Tr}(\Pi^2) + \frac{m^2}{2} \text{Tr}(X^2) + M(a^{\dagger}a + \bar{a}^{\dagger}\bar{a}) + g(a^{\dagger}Xa + \bar{a}^{\dagger}X^T\bar{a})$$

• We focus on the following obsearvable $\omega - M \rightarrow \omega$

$$e^{iM(t-t')} \left\langle \operatorname{T} a_i(t) a_j^{\dagger}(t') \right\rangle_T \equiv \delta_{ij} G(T, t-t') \;.$$

Note that due to time ordering, if t < t' above quantities are zero, so this is retarded Green fn.

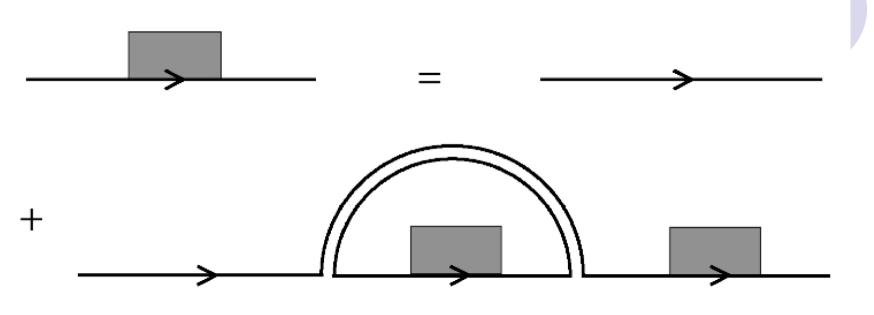

$$G(t) = \int d\omega \tilde{G}(\omega) e^{-i\omega t}$$

• Therefore $\tilde{G}(\omega)$ has no pole in upper half plane

In perturbation expansion,

 $= < \frac{\iota}{\omega + i\epsilon + gX} >_T$ $\tilde{G}(w)$ interaction $= \frac{i}{\omega} + \frac{i}{\omega} \sum_{n=1}^{\infty} \left(\frac{i}{\omega}\right)^n < (-igX)^n >_T$ $X_{ii} = matrix$ free (bare) propagator # op. for matrix X Where thermal sum is defined as; $\langle X \rangle_T \equiv \mathcal{N} Tr \langle e^{-\beta m Tr(A^{\dagger}A)}X \rangle$

Schwinger-Dyson (SD) equation for the fundamental field;

(We have only planar graphs)

• Mathematically $\tilde{G}(\omega) = \tilde{G}_0(\omega) - \lambda \tilde{G}_0(\omega) \left(\int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \tilde{G}(\omega') \tilde{K}_0(T, \omega - \omega') \right) \tilde{G}(\omega)$ • With $\lambda = g^2 N$ and $\tilde{G}_0(w) = \frac{i}{\omega + i\epsilon}$

\tilde{K}_0 is adjoint correlation function which we chose

$$\tilde{K}_{0}(T,\omega) = \frac{i}{1 - e^{-m/T}} \left(\frac{1}{\omega^{2} - m^{2} + i\epsilon} - \frac{e^{-m/T}}{\omega^{2} - m^{2} - i\epsilon} \right)$$

- In zero temperature case, this reduces to free scalar propagator
- Bellow we consider zero temperature/finite temperature case of above SD eq (you will see that structure of the SD eq are totally different between zero and finite temperature)

- Since $\tilde{G}(\omega')$ has no pole in upper half plane, we can close the contour for ω' by going to the upper half plane
- As a result, we pick up only the pole from $K_0(\omega \omega')$

$$\tilde{K}_{0}(T,\omega-\omega') = \frac{i}{1-e^{-m/T}} \left(\frac{1}{(\omega-\omega')^{2}-m^{2}+i\epsilon} - \frac{e^{-m/T}}{(\omega-\omega')^{2}-m^{2}-i\epsilon} \right)$$
pole at $\omega - \omega' = m - i\epsilon$ pole at $\omega - \omega' = -m - i\epsilon$

for SD equation

$$\tilde{G}(\omega) = \tilde{G}_0(\omega) - \lambda \tilde{G}_0(\omega) \tilde{G}(\omega) \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \tilde{G}(\omega') \tilde{K}_0(\omega - \omega')$$

So the SD equation reduces to following recurrence eqs
At <u>zero</u> temperature

$$\tilde{G}(\omega) = rac{i}{\omega} \left(1 - rac{\lambda}{2m} \tilde{G}(\omega) \tilde{G}(\omega - m)
ight)$$

At <u>nonzero</u> temperature

$$\tilde{G}(\omega) = \frac{i}{\omega} \left(1 - \frac{\lambda}{2m(1 - e^{-m/T})} \tilde{G}(\omega) \{ \tilde{G}(\omega - m) + e^{-m/T} \tilde{G}(\omega + m) \} \right)$$

Even though these two equations are similar, the structure of solutions are totally different as we will see

Zero temperature case

$$\tilde{G}(\omega) = \frac{i}{\omega} \left(1 - \frac{\lambda}{2m} \tilde{G}(\omega) \tilde{G}(\omega - m) \right)$$

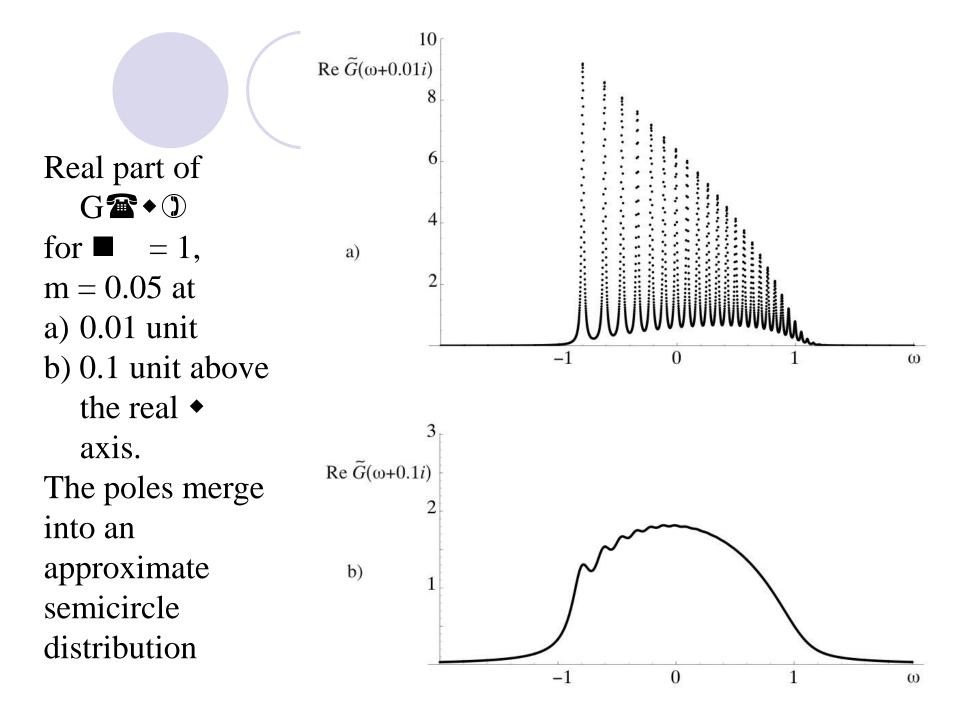

At m = 0 case, SD be algebraic equation and solvable as

$$\tilde{G} = \frac{2i}{\omega + \sqrt{\omega^2 - \nu^2}} , \text{ with } \nu^2 \equiv 2\frac{\lambda}{m}$$

The pole at $\omega = 0$ has been broaden into a branch cut. This is because the mass for a is given by g X and the distribution of X is given by Wigner semi-circle with width

- The Wigner semi-circle for m=0 case splits up into poles at nonzero m.
- To see this, note that if there is branch cut at some •, then the recurrence eq. forces another branch cut at • m, \bullet_{\Box} m, \bullet_{\Box} m, so we have series of branch cut by step of *m*.
- But this contradicts with the fact that at zero T in where theory reduces to free, so should approach $i/\bullet \ll^{1}$ and no branch cut there, unless its amplitudes approaches zero
- We conclude that at zero *T*, spectrum is bunches of poles, no branch cut.

$$\underbrace{\text{Non-zero temperature case}}_{\tilde{G}(\omega) = \frac{i}{\omega} \left(1 - \frac{\lambda}{2m(1 - e^{-m/T})} \tilde{G}(\omega) \{ \tilde{G}(\omega - m) + e^{-m/T} \tilde{G}(\omega + m) \} \right)$$

Again at m = 0 case, with $\blacksquare_{\circledast}$ \blacksquare $\boxdot m (1 - e^{-m/T})$ fixed, it gives

$$\tilde{G} = \frac{2i}{\omega + \sqrt{\omega^2 - (1 + e^{-m/T})\nu_T^2}}$$

Physically eigenvalue distribution is thermally broaden, but still it is power law decay, not exponential.

$$\underbrace{\text{Non-zero temperature case}}_{\tilde{G}(\omega) = \frac{i}{\omega} \left(1 - \frac{\lambda}{2m(1 - e^{-m/T})} \tilde{G}(\omega) \{ \tilde{G}(\omega - m) + e^{-m/T} \tilde{G}(\omega + m) \} \right)$$

Spectrum representation shows negative residues are not allowed along real omega axis

$$\begin{split} \tilde{G}(\omega) &= \mathcal{N} \sum_{A,B} \frac{i}{\omega - E_A + E_B + i\epsilon} e^{-E_A/T} | < A |a| B > |^2 \\ &\equiv \int_{-\infty}^{\infty} d\mu F(\mu) \frac{i}{\omega - \mu + i\epsilon} \end{split}$$

If there is pole, pole must be sandwiched by zero both on the left and right, but this gives contradiction. Therefore the poles which we see at zero temperature are not allowed! This immediately implies that the spectrum is continuous, rather than discrete poles, so there is a chance this shows quasi-normal modes

There are two possibilities

Infinite arrays of branch cut or

Non-zero temperature case

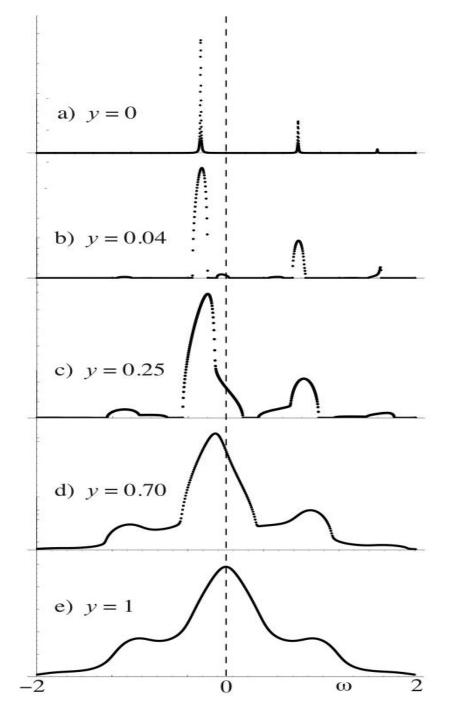

1

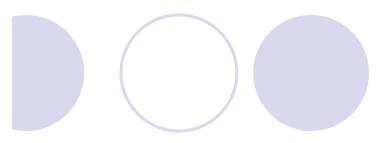

Although this is the model we want, it is still challenging problem to solve this eq. Because <u>this eq. is unstable both along increasing</u> <u>omega and decreasing omega!</u>

$$\tilde{G}(\omega) = \frac{i}{\omega} \left(1 - \frac{\lambda}{2m(1 - e^{-m/T})} \tilde{G}(\omega) \{ \tilde{G}(\omega - m) + e^{-m/T} \tilde{G}(\omega + m) \} \right)$$

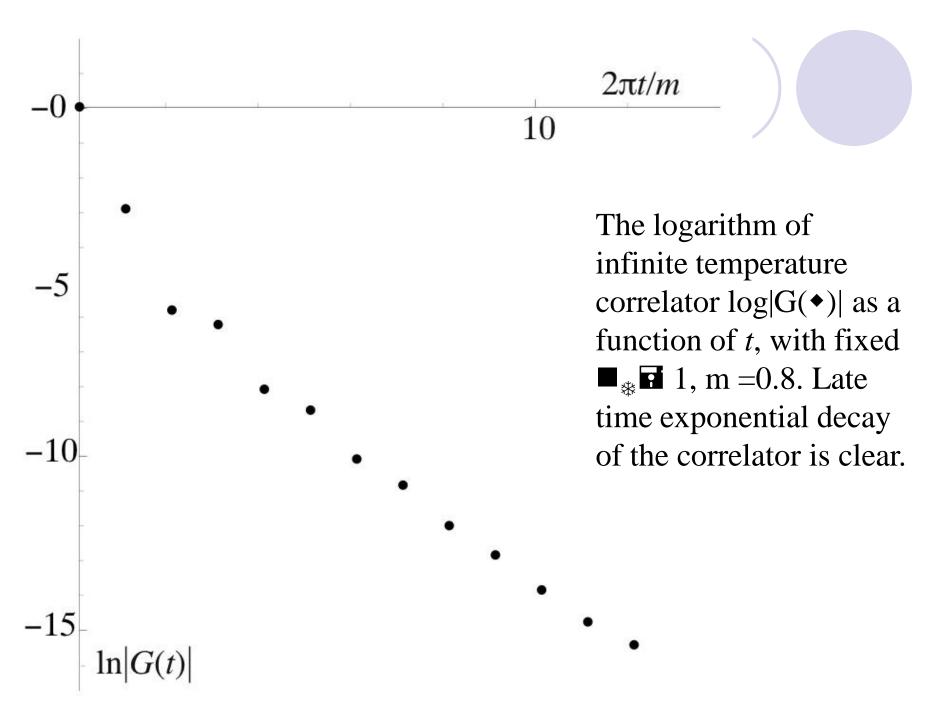

Even numerically this eq. are very hard to solve!

We solved this by fixing \bullet/m , and taking the derivative w.r.t. T, we allow system evolves from zero temperature into finite temperature by solving differential eq w.r.t. *T*

The real part of $G(\blacklozenge)$ as spectrum density with various temperature $y = exp(-\Im m)$ The vertical axis is rescaled. The plot is \blacklozenge axis for slightly above the real \blacklozenge

Non-zero temperature case

Asymptotic behavior of solution

In the large omega, the coupling be weaker, the propagator approaches more to free one, this means magnitude of $\Box F \cong \bullet \textcircled) = \operatorname{Re}[G \cong \bullet \textcircled) \circledast$ approaches 0 at large $\bullet \textcircled{}$

$$F(\omega - m) - \frac{4}{\mu_T^2 |\tilde{G}(\omega)|^2} F(\omega) + e^{-\beta m} F(\omega + m) = 0$$

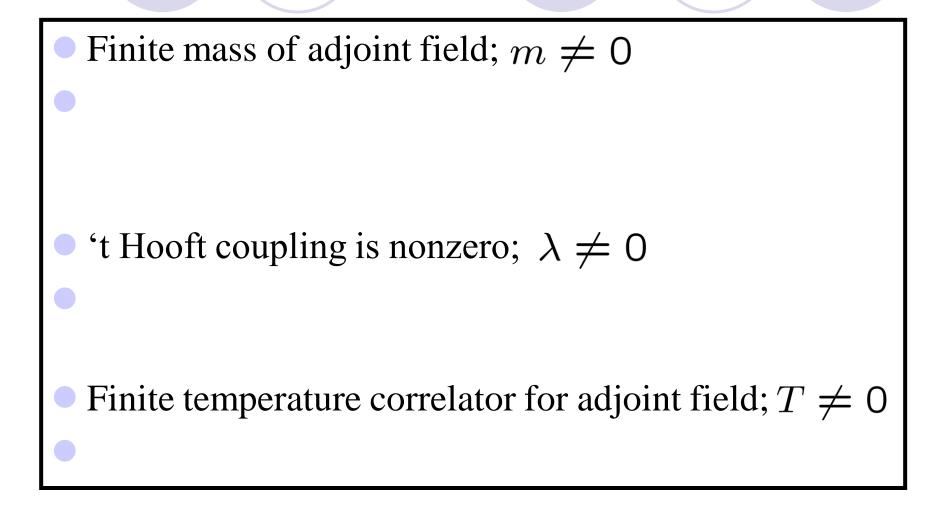

Consistent solution with above boundary condition is;

$$F(\omega)/F(\omega - m) \sim \mu_T^2/4\omega^2, (\omega \to \infty)$$

$$F(\omega)/F(\omega + m) \sim e^{-\beta m} \mu_T^2/4\omega^2, (\omega \to -\infty)$$

Spectral density behaves asymptotically as $|\omega|^{O(-|\omega|)}$

Conditions for quasinormal mode

Conditions for quasinormal mode

- Finite mass of adjoint field; $m \neq 0$
- Black hole microscopic degrees of freedom have finite mass, their wave function is localized at finite scale in space.
- 't Hooft coupling is nonzero; $\lambda \neq 0$
- To escape information into infinite phase space, mixing of states by interaction is crucial.
- Finite temperature correlator for adjoint field; $T \neq 0$
- Black hole should be at deconfinement phase.

Hawking-Page transition and

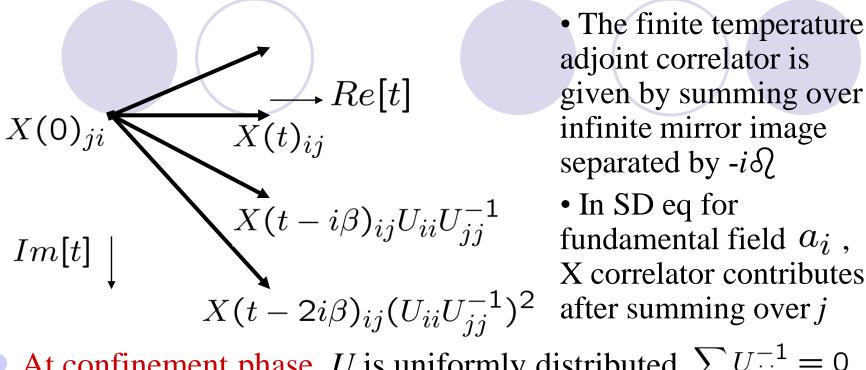

Confinement/Deconfinement transition

- Confinement/deconfinement transition is expected to be connected with Hawking-Page transition (thermal AdS/AdS black hole) in gauge/gravity duality
- In N = O at confinement phase, degrees of freedom are glueball (gauge singlet, closed strings). Their propagate freely at N = O whatever 't Hooft coupling we take. So at this case, theory is in practice free, even though 't Hooft is nonzero.
- At deconfinement phase, degrees of freedom are gluons (gauge non-singlet, open strings, or `string bits'). They still interact at N = 0 if 't Hooft coupling are nonzero.

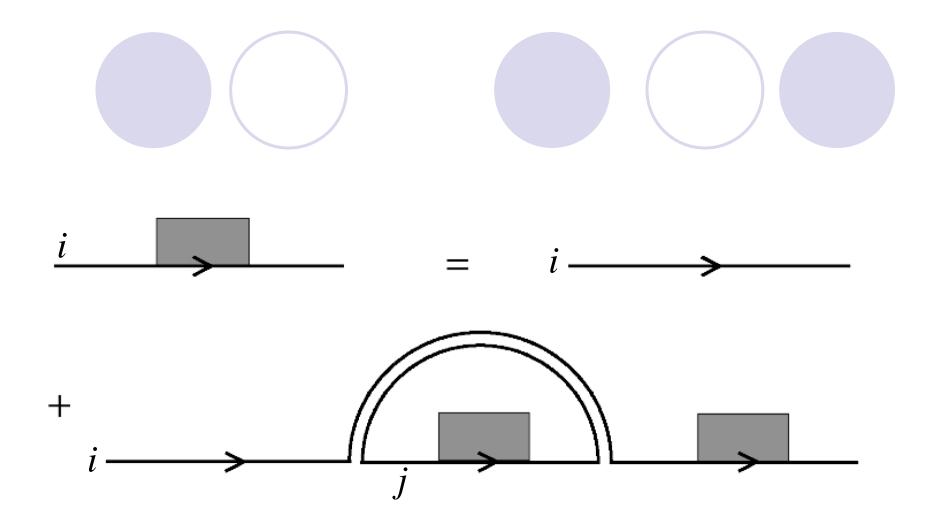

- The system which has dynamical adjoint gauge fields shows Hagedorn transition, which is confinement/deconfinement transition.
- For example, in d=4, *k*=4 SYM shows this transition (Sundborg, Aharony et al)
- This transition is characterized by how the VEV of Polyakov loop operator along time direction changes S

$$< U >_{ij} = e^{\int dt < A_0 >_{ij}} = e^{i\beta < A_0 >_{ii}\delta_{ij}}$$

Zero mode, can be diagonalized

- At confinement phase, U is uniformly distributed, $\sum_{j} U_{jj}^{-1} = 0$ So the adjoint thermal propagator reduces to the <u>zero temperature one</u>, thermal effect cancel out
- At deconefinement phase, especially at very high temperature, U is localized, delta-functionally peaked, then the adjoint thermal propagator reduces to the <u>nonzero</u> <u>temperature propagator</u> we used because $U_{ij} = e^{i\theta}$, $U_{ii}U_{jj}^{-1} = 1$

- So the zero temperature case we studied in our model corresponds to the confinement phase in the real gauge/gravity duality, and the nonzero temperature case, especially very high temperature case, corresponds to precisely the very high temperature deconfinement phase in the real gauge/gravity duality.
- The fact that we don't see quasinormal mode when adjoint X has zero temperature propagator means that we cannot find quasinormal mode when adjoint X is at the confinement phase (=thermal AdS phase).

<u>Conclusion</u>

Conditions for quasinormal mode

- Finite mass of adjoint field; $m \neq 0$
- Black hole microscopic degrees of freedom have finite mass, their wave function is localized at finite scale in space.
- 't Hooft coupling is nonzero; $\lambda \neq 0$
- To escape information into infinite phase space, mixing of states by interaction is crucial.
- Finite temperature correlator for adjoint field; $T \neq 0$
- Black hole should be at deconfinement phase.

Conclusion

<u>Infinite N, deconfinement phase, and non-pert.</u> are responsible for classical black holes

- System can contain infinite information
- Discrete spectrum at pert.
 be <u>continuous</u> by strongly-coupled (= non-pert.)
 effects
- Poincare recurrence never occurs at finite timescale
- Quasinormal mode (exponential decay) is seen due to infinite phase space in <u>deconfinement</u> phase
- Properties of black hole shows up only at infinite N, in finite N, spectrum is discrete, always recurrence appears

Discussion

- To restore the information, finiteness of N is crucial.
- As far as we use the semi-classical approximation, we never restore the information.
- The information loss occurs only at (semi-)classical gravity. In full quantum gravity, we expect 'horizon-like' boundary where information flows only along one side never occur.
- At infinite N, spectrum is continuous, but at finite N it is collections of delta functional peak.
- The continuous spectrum at nonzero *m*, *T*, g^2N and infinite N should split into poles at finite N with spacing $\Omega = \infty \sim \exp(-O(N^2))$

• If we measure the spectrum precisely (measuring each delta functional peak at fixed omega) for the black holes, then we are able to distinguish each microstate of black hole, and this effect is very large, not order $exp(-N^2)$

(Balasubramanian, Marolf, Rozali)

- On the other hand, if we neglect the detail of spectrum, and measure the spectrum in rough way, then we see as if black hole has continuous spectrum.
- In principle, how accurate can we measure the spectrum?
- Uncertainty principle $\mathfrak{L} \cong \mathfrak{L} \land \mathfrak{L} \land h \sim 1/N^{\#}$ prohibits $\mathfrak{L} \cong \mathfrak{L} \land \mathfrak{L} \land$
- As far as we observe 2pt fn., this seem inevitable conclusion

To understand furthermore...

- As we see, thermalization occurs due to the nonperturbative effect by interaction
- On the other hand, our Schwinger-Dyson equation is too complicated to solve analytically <u>even at planar limit</u>
- So <u>non-planar corrections</u> are even more difficult
- To understand better, we would like to have system which shows more analytical control: but still complicated enough to show information loss physics, i.e., continuous spectrum from Schwinger-Dyson equation
- This is the motivation of the second work, where we studied more solvable model, seeing its leading 1/N² corrections
- We saw that leading 1/N² correction does not change the planar physics
- We want to understand 1/N² expansion more
